1.0 INTRODUCTION

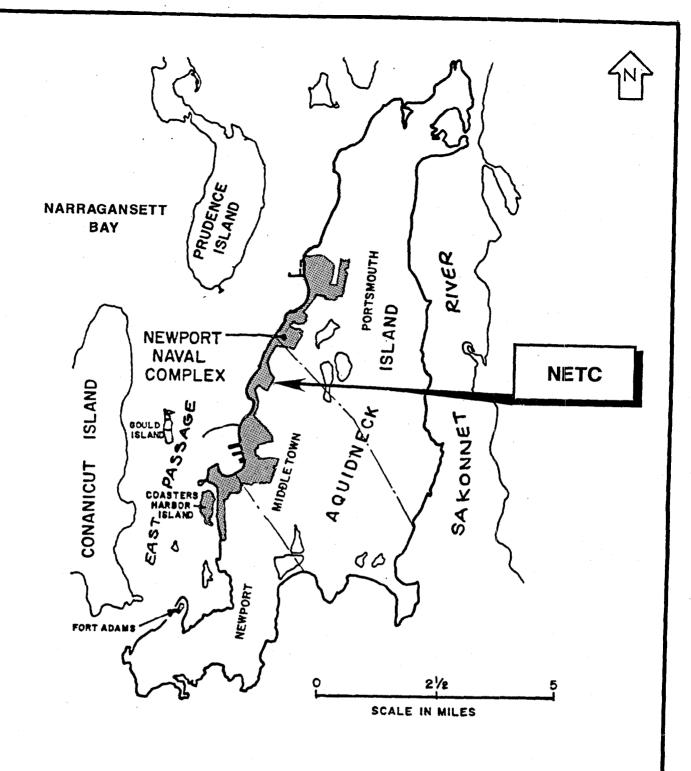

1.1 Project Location and Site Data

The Interim Remedial Action ground water extraction and treatment project location is Tank Farm Five in the vicinity of underground storage tanks 53 and 56 at the Naval Education and Training Center (NETC) in Newport, Rhode Island. Leaking underground oil storage tanks have resulted in contamination to the ground water system necessitating remediation.

NETC Newport is approximately 1,400 acres in size, with portions of the facility located in Newport, Middletown, and Portsmouth, Rhode Island. The site is approximately 60 miles south of Boston and 25 miles southeast of Providence. The facility layout is long and narrow, following the shoreline of Aquidneck Island for nearly six miles (see Figure 1). Tank Farm Five is located in the central portion of the facility, in the town of Middletown, Rhode Island (see Figure 2).

The 85-acre tank farm is the site of eleven underground storage tanks (USTs) numbered 49 through 59. Tanks 53 and 56 are located in the western portion of the Tank Farm Five site (see Figure 3). Each tank is constructed of prestressed concrete and has a capacity of 60,000 barrels (2.52 million gallons each). The tanks are approximately 116 feet in diameter and 33 feet deep. Each tank is covered by approximately four feet of soil and is surrounded by a ring drain which consists of a 12-inch reinforced concrete drain pipe located within a permeable backfill approximately four feet wide. The drain is connected to a sump pump to remove ground water from the backfill area, thereby preventing tank damage or tank flotation.

A paved road provides access to the site, passing between the tank locations in a loop. Other facilities on-site include the recently constructed Fire Fighting Training Area, a small building which was used as an

electrical substation, and a concrete structure apparently used as an oil-water separator. The Fire Fighting Training Area occupies approximately 3 acres in the western portion of the site and is surrounded by a chain-link fence. Gomes Brook crosses the northern portion of the site, and discharges to the Narragansett Bay. Topography generally slopes to the west and north. The central portion of the site in which the tanks are located is gradually sloping and well-drained. During periods of heavy rainfall, runoff from the site was observed to accumulate at the point where Defense Highway crosses Gomes Brook. Ponded water was also observed in a marshy area in the eastern corner of the site. The site is vegetated with grass, brush and some trees. Tank Farm Five is bordered to the west by Defense Highway, to the south by a cemetery, to the east by residences and to the north by Greene's Lane.

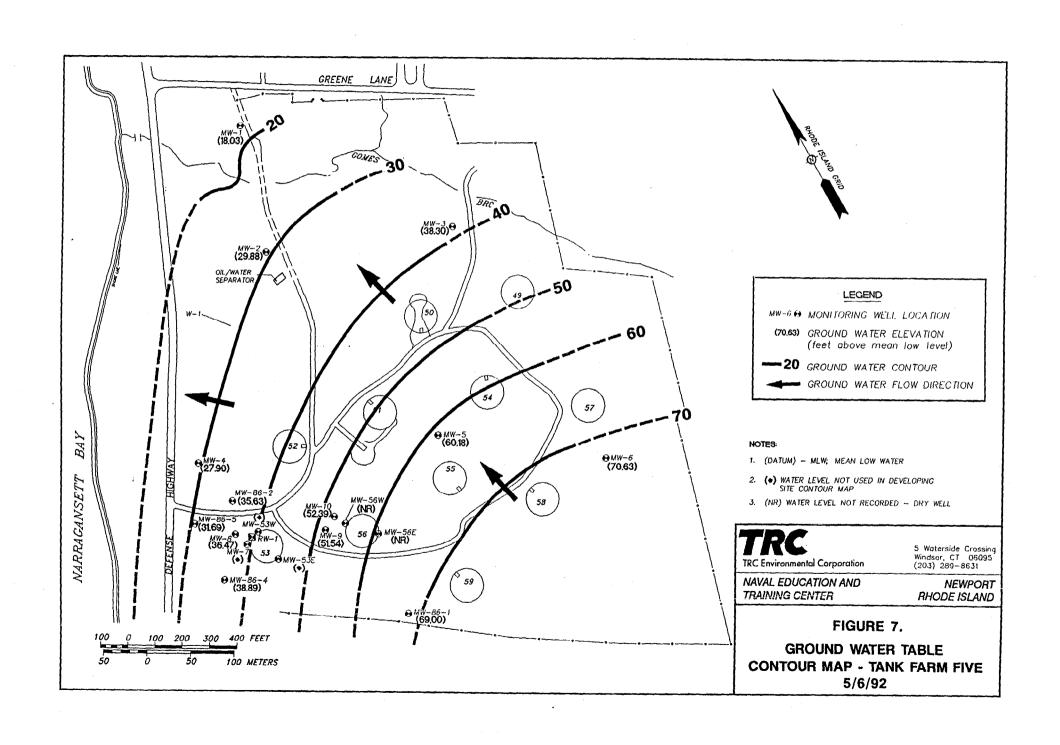

The overburden materials at the site consist of a fill layer around the tanks and native sand and silt, glacial till. The till was encountered in all site borings, ranging in thickness from 1 to 21 feet. The till directly overlies bedrock which consists of gray, highly weathered to competent, slightly metamorphosed shale with quartz lenses. A considerable zone (up to 22 feet) of weathered bedrock overlies the competent bedrock (see Figures 4, 5, 6 and 8).

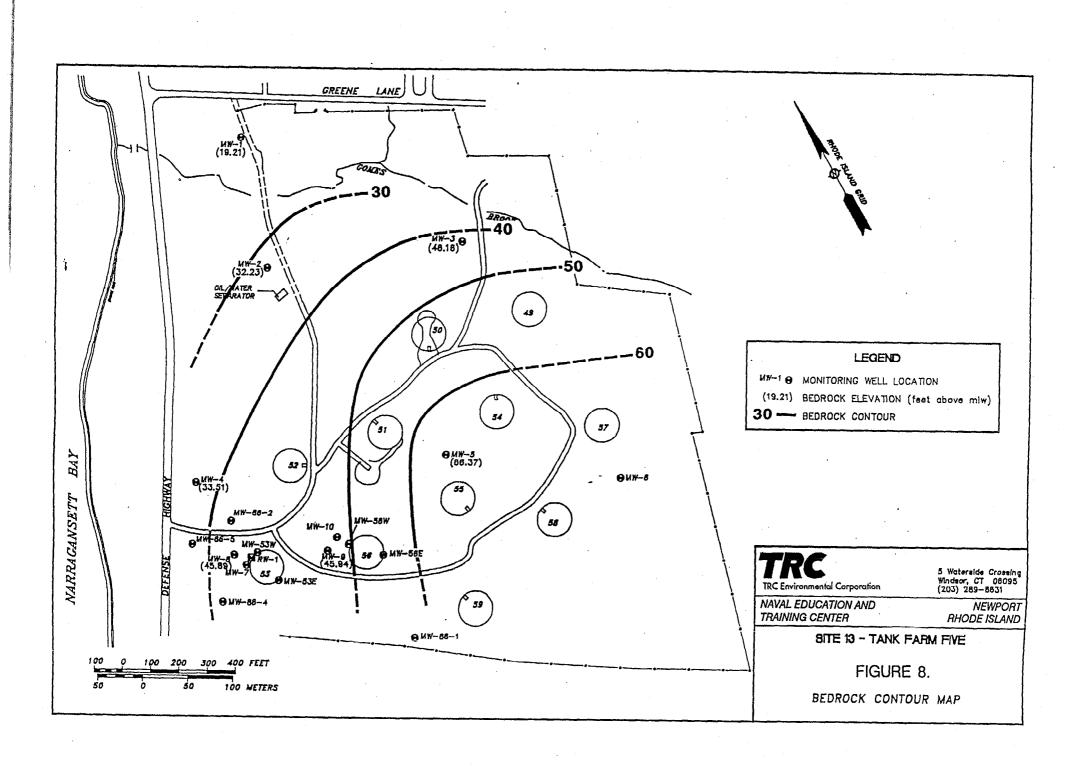

Ground water flow direction for the shallow ground water at Tank Farm Five is generally to the northwest, towards Narragansett Bay in the southern portion of the site, including the area in which Tanks 53 and 56 are located (see Figure 7). In the northern part of the site, ground water flow is to the north, towards Gomes Brook. Piezometer and surface water level measurements indicate that Gomes Brook is a gaining stream (receives discharge from the ground water). Aquifer hydraulic conductivity values were determined from aquifer slug and pump tests. The hydraulic conductivity performed during the

Remedial Investigation on five wells screened in the shallow, weathered bedrock (with the exception of one well screened in till overburden) ranged from 0.16 to 0.21 ft/day. Two subsequent pump tests performed for the Interim Remedial Action on a well screened in the shallow weathered bedrock yielded hydraulic conductivities ranging from 0.14 ft/day to 5.95 ft/day (see Appendix B for detailed information). Horizontal hydraulic gradients in the shallow bedrock and till ranged from 0.0128 to 0.0398 ft/ft. Estimated average linear velocities for shallow ground water range from 0.017 to 0.05 ft/day. contaminated ground water associated with Tanks 53 and 56 is currently flowing away from residential areas and is not discharging to or impacting any surface water bodies. The nearest residential areas are located approximately 1,400 feet to the north-northeast and 1,200 feet to the east-southeast. The current State of Rhode Island ground water classification applicable to the site is class GA-NA. GA indicates ground water sources which may be suitable for public or private drinking water without treatment. NA indicates areas of non-attainment which are known or presumed to be out of compliance with the ground water standards of the assigned classification. The nearest body of surface water off-site is the east passage of the Narragansett Bay. A more complete description of the site can be found in the Remedial Investigation Report on pages 1-23 and 1-24 (TRC, 1991).

Contamination was found in the area near Tanks 53 and 56 during previous investigations and available ground water sampling information indicates that a plume of contaminated ground water is migrating from this source area to the northwest towards Defense Highway.

Ground water sample results indicate the presence of volatile organic compounds (VOCs) and inorganics at levels exceeding the Maximum Contaminant Levels (MCLs), which are standards for drinking water established by the USEPA

under the 1986 Federal Safe Drinking Water Act. Contamination is currently limited to the area near Tank 53 and consists mainly of petroleum-related compounds and VOCs. A layer of floating free product was observed in the Tank 53 ring drain during monitoring well sampling. The presence of low levels of chlorinated hydrocarbons in a downgradient well indicates that migration of contamination is occurring. Base Neutral/Acid Extractable Organic Compounds (BNAs) were also detected from around Tank 53 at levels that do not exceed MCLs. While inorganic concentrations exceeded MCLs in all wells, the highest levels of inorganic analytes were detected in the central portion of the tank farm site.

1.2 Background

The Navy's first permanent activity at NETC Newport was in 1869 when the experimental Torpedo Station at Goat Island was established. In 1941, the Navy began construction of five tank farms with a total of 47 tanks to store fuel oils and other petroleum products with a total storage capacity of 2.8 million barrels. In subsequent peacetime years, on-site facilities were slowly disassembled.

Tank Farm 5 was constructed in 1942 and 1943 and was used for fuel storage from World War II to 1974. In 1975, the Navy began using Tanks 53 and 56 for used oil storage as part of an oil recovery program. Between 1975 and 1982, Tanks 53 and 56 contained used oil for alternate use as heating fuel. In 1982, RIDEM adopted hazardous waste regulations which were applicable to the waste oils in Tanks 53 and 56. Sampling of the water, oil, and sludge in the tanks was conducted in 1983. The sample results indicated that the oil phase in both tanks was hazardous due to the presence of elevated concentrations of lead. The sludge layer in both tanks was also determined to be hazardous due

to the presence of elevated concentrations of lead, cadmium, chromium, barium, mercury, and silver. In addition, the water in Tank 56 was found to contain dissolved hydrocarbon compounds. In 1985, results of ground water samples collected from monitoring wells installed in the ring drains of both tanks revealed the presence of several chlorinated and aromatic hydrocarbons and trace concentrations of mercury. Cadmium was also detected in one ground water sample from the ring drain of Tank 56. Subsequent investigatory activities conducted in 1986 confirmed the presence of VOCs in the Tank 53 ring drain and in the ground water 150 feet downgradient of Tank 53.

On September 10, 1985, NETC was issued a Hazardous Waste Facility Permit by the RIDEM. In addition to permitting the two hazardous waste storage areas, the permit stated that Tanks 53 and 56 were to be removed and closed in accordance with hazardous waste regulations, as well as RIDEM requirements for underground storage tanks for oil and hazardous substances.

On November 21, 1989, NETC Newport was placed on the USEPA's National Priorities List (NPL). Private-sector NPL sites are eligible for funding from the national environmental trust fund called Superfund. Investigation and cleanup of DOD sites, such as NETC Newport, are funded through the Defense Environmental Restoration Account (DERA).

1.3 Remedial Investigations

In January 1990, oil was observed leaking out of the gauging chamber of Tank 53 and onto the ground. Although the actual cause of the release was unknown, it was suspected that it may have resulted from, or been compounded by, construction projects underway in Tank Farm 5 close to Tank 53. RIDEM issued an Immediate Compliance Order which required the Navy to remove the contents of Tank 53, begin remediation of contaminated ground water and soils

surrounding the tank, and initiate an investigation to determine the extent of oil contamination in the vicinity of Tanks 53 and 56.

In the spring of 1990, TRC Environmental Corporation (TRC) installed additional monitoring wells and collected soil, water, and tank content samples to determine the presence and extent of contamination in and around Tanks 53 and 56. The oil product samples contained high concentrations of chlorinated and aromatic hydrocarbons, base/neutral/acid extractable compounds (BNAs) and several metals. Water samples from both tanks contained detectable concentrations of chlorinated and aromatic hydrocarbons, semi-volatile organics, and several heavy metals. Surface soil samples showed low concentrations of petroleum hydrocarbons and lead. Five soil boring samples contained detectable concentrations of both BNAs and petroleum hydrocarbons. Ground water sample results indicated the presence of floating hydrocarbon product and ground water contaminated with chlorinated and aromatic hydrocarbons and polynuclear aromatic hydrocarbons in the vicinity of Tank 53.

Pursuant to RIDEM tank closure requirements in 1992, the Navy completed the removal of the sludge, oil and water layers from Tanks 53 and 56. After removal of the tanks contents, the tank walls were steam-cleaned. An air stripping system with activated carbon was constructed to treat the tank's water contents as well as the contaminated ground water as it was removed from around the tanks. With the completion of this work in 1992, the air stripping system was removed. Confirmatory samples (to verify steam cleaning operations) of concrete from inside the tanks have been analyzed for Toxicity Characteristic Leaching Potential (TCLP) and have been found to be below detection levels.

Several pumping wells were installed around these two tanks prior to removal of their contents to avoid tank damage and potential tank flotation

due to hydrostatic pressure from adjacent ground water. A sump pump, activated by an increase in hydrostatic pressure, was installed to remove ground water from the ring drains around the tanks during periods of high ground water flow, e.g., heavy rainfall. An air stripping system with activated carbon was constructed to treat the tank's water contents as well as the contaminated ground water as it was removed from around the tanks. With the completion of this work in 1992, the air stripping system was removed.

Presently, ground water from the ring drains is being pumped and transferred to another nearby tank, pending approval of a permit modification with the City of Newport for discharge into their wastewater treatment plant.

Remediation of soil contamination around Tanks 53 and 56 is being addressed as part of the Resource Conservation and Recovery Act (RCRA) tank closure activities previously discussed. The Navy has recently initiated an investigation that will determine the horizontal and vertical extent of soil contamination. This information will be utilized to proceed with soil remediation in accordance with RIDEM's tank closure requirements.

The Phase I RI Report is currently being finalized. This report addresses the investigation activities conducted and findings to date at Tank Farm Five. The general purposes of the overall investigation were to:

- determine the presence, nature and extent of contamination resulting from historic site activities, including on-site and off-site impacts to soils, ground water, surface water, sediment and biota;
- identify potential contaminant migration routes;
- identify potential receptors of site contaminants; and
- characterize related environmental impacts and potential human health risks.

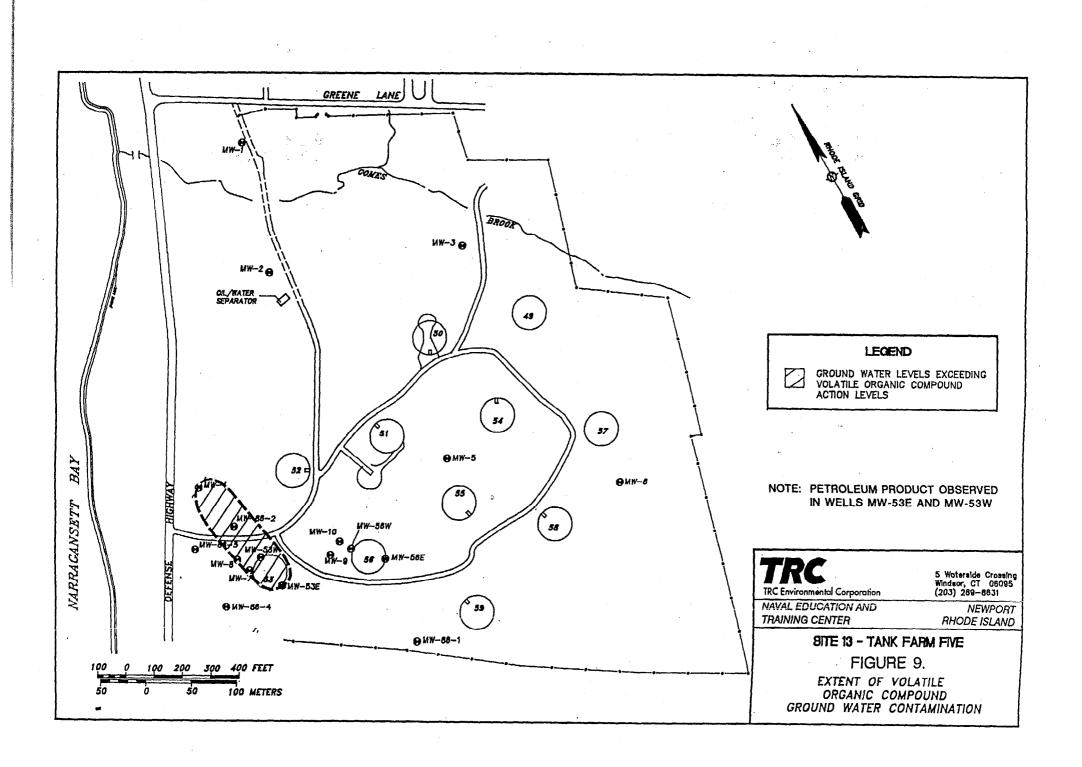

The Navy implemented a field sampling program to evaluate the ambient air and radiological surveys, geophysical surveys, soil gas surveys, and the collection and analysis of soil, sediment and ground water samples. A total of 88 samples were collected from Tank Farm Five during the Phase I RI.

Because of additional underground storage tanks (USTs) and an oil/water separator at the site, it was suspected that there may be additional sources of ground water contamination across Tank Farm Five. In addition to seven wells previously installed, six new monitoring wells were installed and sampled. The additional wells were added to more thoroughly investigate the nature and extent of ground water contamination and the effect of Gomes Brook on the site hydrology. Five additional wells were installed under tank closure investigation activities around Tanks 53 and 56 at Tank Farm Five.

1.4 Purpose

This interim remedial action is intended to contain ground water contamination in the vicinity of Tanks 53 and 56 and to prevent it from migrating further toward Narragansett Bay (see Figure 9). As part of this containment action the contaminated ground water pumped from the site will be treated on site and discharged into the public sanitary sewer system for conveyance to the local wastewater treatment facility. The contaminated ground water extraction will stabilize the migration of contaminants in the ground water until a final remedy has been chosen. An interim remedial action is not intended to be a final remedy but should be consistent with the final remedy chosen for that site.

Using the information gathered from site studies, the Navy identified objectives for the interim remedial action for cleanup of contaminated ground water around Tanks 53 and 56. The cleanup objectives are:

- 1. to minimize further migration of the contaminated ground water;
- to minimize any future negative impact to Gomes Brook and Narragansett Bay resulting from discharge of contaminated ground water;
- to reduce the potential risk associated with the future ingestion of contaminated ground water; and
- 4. to reduce the time required for restoration of the aquifer.

As an interim step to meeting these objectives, the Navy proposes to extract and treat ground water from the most highly contaminated portion of the plume. This interim remedial action, which is intended to quickly respond to the plume of contamination in the vicinity of Tanks 53 and 56, will eventually become part of the overall remediation strategy for Tank Farm Five and NETC Newport as a whole. Therefore, the interim remedial action selected for ground water remediation must be consistent with the cleanup goals established for ground water site-wide and for the final remedy for the Tank Farm. The Navy's long-term cleanup goals for reducing contamination in ground water at NETC Newport are to meet drinking water Maximum Contaminant Levels (MCLs), Maximum Contaminant Level Goals (MCLGs), or risk-based levels for compounds for which drinking water standards have not been set.

Because the purpose of the proposed action is to manage migration and begin cleanup of the contaminated ground water in the vicinity of Tanks 53 and 56, and is not meant to be the permanent remedy for Tank Farm 5, the Navy has assumed that the action will last for five years. After five years (or after the ROD for the final remedy), the Navy and the regulatory agencies will review the monitoring data and evaluate the effectiveness of the interim action. If the interim action is performing in accordance with project goals, the interim action could become part of the overall site remedy. If modifications need to be made to the extraction or treatment systems, they could be incorporated into the final remedy for the site.

2.0 REMEDIAL PLAN OVERVIEW

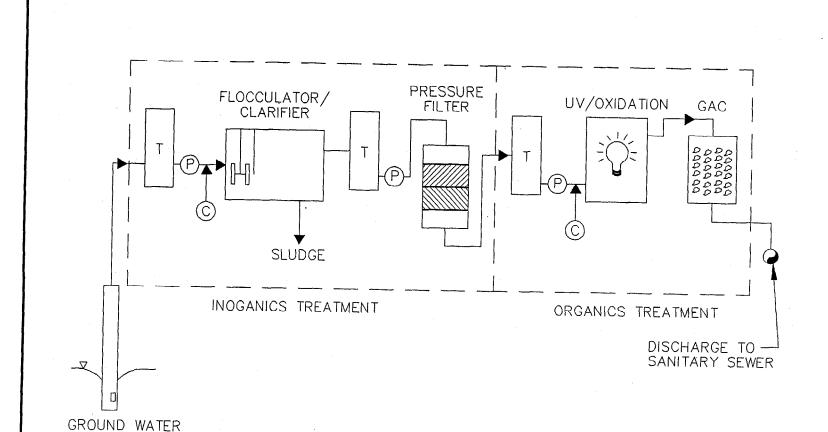

2.1 Summary

As detailed in the Record of Decision, the proposed treatment process includes removal of metals and volatile organic compounds (VOCs) from the water as follows: dissolved metals and inert suspended solids concentrations in the extracted ground water will be significantly reduced using a coagulation/filtration process so that they do not interfere with the VOC treatment process. Metals removal is accomplished by adding treatment chemicals to precipitate the metals out of solution and remove settleable solids in a clarifier tank. The remainder of the precipitated metals/solids will be separated from the water by passing the flow through filters. Following filtration, the water will be injected with an oxidant and pumped into a reactor exposing the contaminants to ultraviolet (UV) light to destroy VOCs. Additional treatment with a granular activated carbon adsorption system ensures that the discharge water meets the pretreatment standards of the publicly owned treatment plant (POTW) before discharge to the sanitary sewer. A block flow diagram of the treatment process is shown as Figure 10.

Existing wells and additional observation wells will be monitored during the interim remedial action to confirm the capture of contaminated ground water (see Figure 4). A monitoring program will be developed during final design and submitted for regulatory approval.

2.1.1 Discharge Requirements

Discussions with the City of Newport POTW officials indicate that the plant can accept the predicted minor hydraulic and chemical loading from this Interim Remedial Action. The POTW has established pretreatment standards for inorganic contaminants and a limit of 2.0 mg/l for "Total Toxic Organics" (EPA

TREATMENT PROCESS
BLOCK FLOW DIAGRAM

Methods 8240 and 8270 for Volatile and Semi-Volatile Organics, respectively). Table 1 shows the expected influent concentrations from the wells (by calculating an average value from the sampling results of wells in the area of proposed ground water extraction) and the concentration limits for discharge to the POTW.

2.2 Ground Water Extraction

er-ori

Based on the results of previous sampling to determine the location of the contaminated plume, extraction wells have been located at the leading edge to control further downgradient migration. Additionally, a row of extraction wells has been sited adjacent to the downgradient side of Tank 53 to intercept contaminant migration (see Figure 9).

Pump test results and capture zone modeling have determined the spacing and predicted withdrawal rates of the extraction wells. Data from the aquifer testing and modeling indicates a well spacing of 10-22 feet will yield a flow range of 0.25 to two gallons per minute (gpm) from each well. Based on this information, eight extraction wells have been planned along the downgradient extent of the plume and five extraction wells near Tank 53 to a depth of 100 feet producing a predicted combined pumping rate of 3.3 to 26 gpm. (Detailed information regarding ground water extraction is contained in the Aquifer Testing and Modeling Report in Appendix B). After well construction, the Contractor will be required to perform a pumping test to determine maximum and optimum well yields.

The extracted ground water will be discharged from each well with an electric submersible pump to a common collector main flowing to the treatment building.

2.3 Inorganic Contaminants Treatment

The extracted ground water will empty into an atmospheric pressure equalization tank. A caustic hydroxide solution will be added to raise the pH to ≈8.5 producing conditions where metals become less soluble and easier to precipitate as solids. A transfer pump will deliver the ground water to a flocculator/clarifier (F/C) treatment unit. In the pressure line, a flocculent, coagulant and oxidizing agent will be injected to enhance particle formation and break down any chelated metals that are complexed with organic compounds that would not precipitate otherwise.

Bench scale testing of the metals treatment process will be required of the equipment manufacturer to optimize the chemical loading requirements. It may be possible to reduce the coagulant feed rate because the high iron concentration may produce particles suitable for flocculation. Hydrogen peroxide has been selected as the oxidizing agent because it will already be on-site for use with the UV/oxidation system and because of its strong oxidizing capabilities. The feed rate will be optimized during system operation.

A rectangular F/C unit utilizing upflow inclined plate settling has been selected for the high relative settling rates and compact design. A clarifier is necessary because of the high suspended solids, iron and other metals that exist in the ground water that must be removed. Paddles in the flocculator zone will slowly mix the chemicals and precipitates of metal hydroxides will form. Settleable solids will collect on the clarifier bottom to be pumped to a sludge thickening tank. A filter press will be batched as necessary to reduce sludge volume for disposal. The sludge will be tested using the TCLP extraction method to determine if it has to be disposed of as hazardous waste. Filtrate water from the sludge process will be recycled back to the head of the treatment system.

Clarified water from the F/C unit will flow to a storage tank necessary to prime a transfer pump prior to pressure filtration.

Dual media pressure filters will remove unsettleable and other fine particles necessary to meet discharge limits and final pretreatment requirements to prevent fouling the UV/oxidation process. When the solids have clogged the filter bed to the extent that head loss becomes unacceptable, a backwash process will be initiated with high reverse flow rates to remove the particles. The backwashed water will be recycled to the influent equalization tank via the sludge thickener tank to remove any solids.

Alternative means of metals contaminant removal were considered during the screening design process. Most notably the membrane filtration technology offered the benefits of physical removal with minimal chemical addition and therefore less sludge generation. However, the relatively high solids loading rate of the water to be treated results in an operating inefficiency to the extent that the proposed "conventional" removal is estimated to be more cost effective.

2.4 Organic Contaminants Removal

Filtered water from the inorganics treatment process will then be cycled through the ultraviolet light chamber where hydrogen peroxide will be added for oxidation of organics. In this high energy (predicted 30 kilowatt demand) environment, hydroxyl radicals are formed which act to break down organic contaminants into simpler, non-hazardous substances such as carbon dioxide, water, salts, sulfates, nitrates, and organic and inorganic acids. UV/oxidation works well to destroy most organic contaminants but requires significantly longer residence times with aliphatic alcohols and saturated hydrocarbon compounds such as 1,1,1-trichloroethane and methylene chloride.

Rather than oversize the UV reactor for these few compounds resulting in excessive electrical energy useage, a granular activated carbon (GAC) absorption system will be utilized to reduce the remaining untreated organics concentration. The UV/oxidation unit will be sized to remove nearly all of the VOCs from the water. The usage rate of GAC is expected to be relatively low thereby minimizing the frequency of carbon changeout and regeneration.

2.5 Treated Water Discharge

The final treated ground water will be tested for compliance with the POTW pretreatment permit standards and discharged by gravity to the sanitary sewer in the vicinity of the Fire Fighter Training Center.

2.6 Support Facilities

All treatment units and systems will be equipped with appropriate instruments and controls to protect equipment, monitor flow and treatment efficiency. Control interlocks will shut down the entire treatment system for safety and issue an alarm signal in a breakdown condition.

Extraction wells will be equipped with float controls to protect against motor burnout and flow meters and throttling valves to enable measurement and adjustment of flow.

The treatment system will be housed in a pre-engineered metal building with heating and ventilation to minimize exterior environmental stress that can affect treatment processes.

Fire protection will be provided sufficiently by the existing water main and fire hydrant system near the treatment building. Fire extinguishers will be placed appropriately in the building. There are no flammable chemicals which will be used inside the building. This coupled with the small size

(<5,000 sq. ft.), low occupancy and fire resistive construction eliminates the need for a sprinkler system.

2.7 Monitoring Plans

Routine sampling and analysis of the ground water in and adjacent to the contaminant plume will be performed on a quarterly basis to monitor the changes and reduction in contaminant concentrations. Water level measurements in observation wells will be used to monitor the effective capture zone.

Well flow rates will be recorded to enable a hydraulic analysis of the ground water system and determine necessary adjustments.

Sampling ports will be installed between treatment unit process steps to enable testing for monitoring and optimization of chemical feed and loading rates. A laboratory setup at the treatment plant will be equipped to allow routine chemical analysis (spectrophotometry). Complete testing of the treatment plant effluent is proposed to be performed at an approved laboratory for compliance with the POTW permit conditions. Table 2 lists the proposed analytes to be tested:

TABLE 2
TREATMENT SYSTEM EFFLUENT MONITORING

Parameter	Frequency	Parameter	Frequency

Zinc	Monthly	рН	Monthly
Cyanides	Monthly	-	1

The proposed monitoring location is the sampling port at the end of the treatment system inside the new treatment building.

2.8 Free Product Source Recovery

Free product has been identified in the ring drain at Tank 53 during the remedial investigation phase. The record of decision does not require source removal of free product and the current design package does not include any provision for free product recovery.

A separate study is underway regarding clean-up options for source removal at Tank 53. A draft report presenting findings and recommendations is in preparation.

2.9 Permit Review

The Navy has applied for an Industrial User Discharge Permit for the Newport POTW (see Appendix C). Table 3 contains an evaluation of other permits that may be applicable to the Interim Remedial Action.

TABLE 3

GROUND WATER TREATMENT AT TANK FARM FIVE - NETC NEWPORT PRELIMINARY PERMIT EVALUATION MATRIX

Permit Category	Permit Name	Regulatory Citation	Permit Description	Project Applicability
AIR	a. Equipment Registration	RI Air Pollution Control Regulations No. 9, 3/93	Registration of air pollution control devices	No
	b. Permit to Construct, Install, Modify or Operate	RI Air Pollution Control Regulations No. 9, 3/93	Permitting of air pollution control devices	No
HEALTH & SAFETY	a. OSHA Confined Space Permit	29 CFR 1910.146(b)(23)(i) through (iii)	Entry into a "permitted" confined space	No
SAI DI I	b. Hazard Operation Permit	U.S. Department of the Navy, Fire Division	Burning, cutting, or welding operations	No
	c. Gas-Free Certification	U.S. Department of the Navy, Fire Division	Burning, cutting, or welding in a hazardous area	No
UNDERGROUND STORAGE TANKS	a. Underground Storage Tank Registration Notification	Section 8.00 of the RI Regulations for Underground Storage Facilities used for Petroleum Products and Hazardous Wastes	Registration of underground petroleum and hazardous waste storage tanks	No
WATER MANAGEMENT	a. RI Pollutant Discharge Elimination System (RIPDES) Permit	Chapters 46–12, 42–17.1, and 42–35 of the RI General Laws, 1956 as amended	Discharge of wastewater to a surface water body	No
	b. Order of Approval: RIPDES	Chapters 46-12, 42-17.1, and 42-35 of the RI General Laws, 1956 as amended	Emergency discharge of wastewater to surface water body	No
	c. General Permit for Stormwater Discharges Associated with Construction Activity	Rule 31 of the RIPDES Regulations	Discharge of stormwater via a point source at construction sites which disturb > 5 acres of land	No
	d. Order of Approval: Underground Injection Control (UIC)	Chapter 46-17 and 46-12 of the RI General Laws, 1956 as amended	Discharge of wastewater to ground water	No
	e. Newport POTW Industrial User Permit	Chapter 46-12, 42-17.1, and 42-35 of the RI General Laws, 1956 as amended	Discharge of wastewater to POTW	Yes
WETLANDS	a. Application for Preliminary Determination	Rule 4.00 of Section 2–1–18 through 2–1–24 of the RI General Laws	Determination whether wetlands requirements are or are not applicable to this project.	No
	b. Permit to Alter Freshwater Wetlands	Rule 8.00 of Section 2-1-18through 2-1-24 of the RI General Laws	Permit which is issued through RIDEM to allow alteration of wetlands	No

3.0 BASIS OF DESIGN AND CALCULATIONS

3.1 Introduction

Design criteria and calculations are presented for the various design disciplines involved in the Ground Water Treatment Interim Remedial Action, all in accordance with Navy Guidance Manuals.

3.2 Civil Engineering Design

3.2 Civil Engineering Design

I. Basis of Design

Civil engineering aspects of the project include ground water extraction wells and piping, water supply and sanitary sewer system extension, paving, drainage and miscellaneous site improvements. The extraction wells are a major component of the Interim Remedial Action to control the migration of contaminated ground water. The other civil engineering facilities are minor in scope and primarily in support of the treatment system and building services.

The project site is a west-facing wooded hillside of moderate slope (3-10%) falling to Narragansett Bay. Adjacent to the site the Navy constructed a Fire Fighting Training Center (FFTC) in 1990.

An existing 8-inch and 12-inch diameter water supply system at the site was upgraded for the construction of the FFTC and will be adequate to serve the minor additional demands of this IRM Treatment System. A pressure/flow test has been conducted at the site to obtain design data for water service and fire protection capacity.

Sanitary sewers were extended to the FFTC from the existing NETC sewer system. Sewage from this area flows by gravity in an 8-inch diameter line to a pump station located near the intersection of Greene's Lane and Defense Highway. The gravity flow portion of the system is presently working satisfactorily with no reported problems and should be adequate to serve the minor additional demands of the IRA Treatment System. An 8-inch diameter PVC pipe with manholes is planned to connect to the existing sanitary sewer at the FFTC. The pump station/force main portion of the sanitary sewer system is currently under study with upgrades expected.

Storm water run-off will be diverted away from the Treatment Building with the use of grass swales designed for a 100-year storm. The Treatment Building has been located between Tanks 53 and 56 in an area clear of underground utilities. The location was selected so that treated water effluent can flow by gravity to the existing sanitary sewer at the FFTC. It is also proximate to other zones of ground water contamination that may be included in the treatment process in the future.

An asphalt concrete driveway extension is planned to the Treatment Building area so that plant operators and suppliers can gain all weather access. There is space for two vehicles and one delivery truck in the parking area. A gravel roadway is shown traversing remote portions of the site to allow access and maintenance of the extraction wells.

The Treatment Building area will be protected by a 7-foot high chain link fence. Fire alarms at the site will be wired to the central fire station.

Designs are based on standard professional engineering practice and criteria from the Navy Design Manuals and Handbooks, American Society of Civil Engineers, American Water Works Authority, Water Environment Federation (formerly Water Pollution Control Federation), etc. The following references have been used for design:

INTERIM REMEDIAL ACTION
TANK PARM FIVE
NETC, NEWPORT, RI

CONTRACT No. NG2472-92-C-0056 DATE 19 JAN 1993

BY R. Nault

CHK'D REV 30 APR 1993

SUBJECT a. GROUND WATER EXTRACTION WELL SYSTEM

Based on preliminary well data, the flow rate from each well is expected to be 0.25-2 gpm with a spacing of 10-22 ft. The seveen interval will extend from the unconsolidated overburden into the fractured bedrock to a depth of 100 ft. The ground water table flucuates between 20-30 ft below the surface and a drawdown of 60 ft. can be provided.

The wells will be 4"\$ with stainless steel screen and sand pack. A stainless steel cleetric submersible well will be installed and each well will have a valve pit containing a flow meter, throttling valve, pressure gage and sampling tap.

13 individual wells will be tied into a common polyethylene collector pipe to the treatment building. Pipe size has been determined such that velocity will not exceed 5 feet per second (minsize=1/2") (as per Mil Handbook 1005/7) to reduce evergy losses and control water hammor. A table can be established for plastic pipe:

PIPE SIZE	MAXIMUM FL	<u>ow</u>
	15 epm	
1 1/4"	22 GPM	
1/2"	32 GPM	
21	52 GPM	
3"	115 GPM	
4"	200 GPM	the same forces of the same of

Even the smallest Grundfos Pump Model (1/3 kp) can deliver 2 opm at 240' TDH. Thus this type pump will work here and in all other site wells. The throtling valve will have to be closed somewhat to induce additional head loss to produce the desired steady flow from the wells. The well level sensors will be arranged such that a minimum drawdown at the wells of 8 feet will provided. This will ensure that sufficient gradient exists at all times to provide plume capture. The pumps will operate at a minimum flow of 1.2 pm to profect them from burnout which may result in cycling if the aguifer cannot yield the pump flow.

Example:

(A) 100 ft. of 2" plastic pipe with one (1) 90° elbow and one (1) swing check valve.

90° elbow — Equivalent to

5.5 ft. of straight pipe

Swing check — Equivalent to

13.0 ft. of straight pipe

100 ft. of pipe — Equivalent to 100.0 ft. of straight pipe

118.5 ft. = Total equivalent pipe

Figure friction loss for 118.5 ft. of pipe.

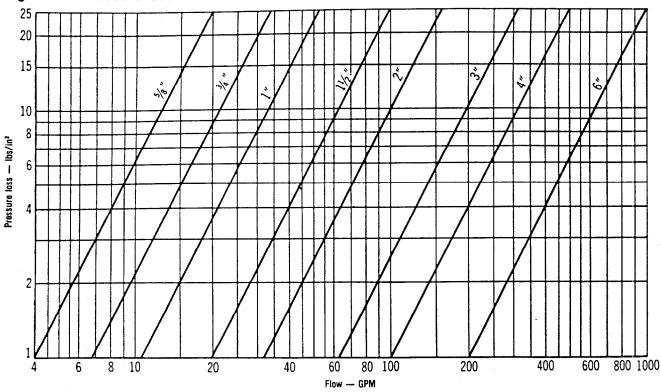

- (B) Assume flow to be 80 GPM through 2" plastic pipe.
- 1. Friction loss table shows 11.43 ft. loss per 100 ft. of pipe.
- 2. In step (A) above we have determined total ft. of pipe to be 118.5 ft.
- 3. Convert 118.5 ft. to percentage 118.5 + 100 = 1.185
- 4. Multiply 11.43

x 1.185

13.54455 or 13.5 ft. = Total friction loss in this system.

SHEET NO. 4 OF 9
PROJECT NO.
DATE 19 JAN 1993
BY R. Nault
CHK'D REV 30 APR 1993

SUBJECT b. Water Supply System

The new service line will be 11/2"\$ copper tubing. The existing 8" main to the FFTC will be wet-tapped and a corporation stop and curb stop/box will be installed. (Note that the FFTC main was selected instead of the closer Tank Farm main because the Tank Farm line is not often used which may result in water quality problems) The service line will be routed to the treatment building where a reduced-pressure principle backflow preventer and water meter will be installed inside. The exterior line will have a minimum cover of 4-2" which is below the extreme frost depth for NETC. The projected building water use is: Domestic 50 gpcd/worker/shift x 4 = 200 gpd Clean-Up (Wash hose) 5 gpm × 20 min /day = 100 gpd TOTAL = 300 ppd

The projected peak day flow (using a factor of 4)

PEAK DAY = 1,200 gpd

The projected instantaneous* flow = 25 gpm *see Plumbing

The water system flow fest determined that the static hydrarlic grade line in the area = Elev 243± Thus with the building at Elev 74 that results in a pressure head of 73 ps; ±. The head loss in 260' of 11/2" copper @ 25gpm = 2.6ps; resulting in 70 ps; ± at the building V

TRC Environmental Corporation

SHEET NO 5 OF _ 9						
PROJECT NO						
DATE 19 JAN 1993						
BY R North						
CHKID PEV 30 APR 1993						

SUBJECT C. Sanitary Sewer System

An 8" of PVC sanitary sever line will be extended from the existing system to the Treatment Building. The minimum slope in the down stream line is 0.50 ft/100 ft to produce scour velocities of at least 2.5 feet per second. Connection to the existing system will be made by core-drilling an existing manhole, re-forming the invert and scaling with a neopreme boot.

The predicted flow in the samilary sever system will be from the Treatment effluent and domestic wastewater:

Treatment Process
50 ppm x 1440 min/day

72,000 gpd

Domestic / Building Services

300 ppd

TOTAL

72,300 gpd

The capacity of an 8"\$ line at minimum slope of 0.50 ft/100 ft is 600,000 gpd. The peak flow from the Treatment Building will be

Treatment Process × (1.2 pump factor)
72,000 gpd × 1.2 = 86,400 gpd

Domestic/Building (Peak Factor = 4) = 1,200 ppd 300 ppd' x 4 TOTAL = 87,600 ppd

.. OK Peak Flow << Pipe Capacity

SUBJECT d. Storm Water Management

A swate will be constructed around the uphill side of the Treatment Building and roadway to divert water away. The swale has been sized for a 100 year storm event because of the hazard associated with chemical storage (per Mil Handbook 1005/3). The swale will be vee-shaped with 4:1 side slopes so it can be moved. It will have an effective depth of 1.5 and an allowable water depth of 1.0' to yield freeboard.

Hydrology - using the Rational Method Q = C & A
Two swales are proposed

Swale 1

Drainage Area, A = 0.93 acres C=0.30 Woodland
Time of Concentration Tc = 25 min

300'of overland flow S=3.390 Forest, Bush
150' of concentrated flow S=670 Bush
Rainfall Intensity, i,= 3.9 in/hr from Chart

Peak Flow, Q = 0.30 x 3.9 x 0.93 = 1.1 cfs

Swale 2

Drainage Arca, A = 0.63 acres C=0.30
Time of Concentration, Tc = 25 min

(same flow conditions as above)

Rainfall Intensity, C = 3.9 in /hr

Peak Flow, Qz = 0.30 x 3.9 x 0.83 = 0.7 cfs

BY	R. Nault	
CHK.D	PEN 30 APR 1993	

SUBJECT e. Roadways

The parking area and access driveway have been designed with a 3" asphalt concrete wearing surface on a 6" base and 8" subbase to handle the delivery truck projected load consistent with CBR values. The maximum slope is 6% and the minimum horizontal curve is 50 ft radius. Traffic will only be the result of treatment plant operators and delivery vehicles. A gravel road will be constructed in the remote areas of the extration well system to facilitate monitoring and main tenance of the wells.

SHEET NO 9 OF _ 9	
PROJECT NO.	
-	
DATE_	20 JAN 1993
BY	R. NauH
CHK.D	REY 30 APR 1993

SUBJECT f. Site Improvements

The treatment building area will be protected with a 7 ft high chain link fence (as per Mil Handbook 1005/12). Access will be through double 12 ft wide swing gates at the entrance to the parking area.

Silt fencing will be required on the downgrodient side of all fills and limits of grading to reduce sedimentation and erosion during construction.

Turf will be established over all disturbed areas with jule-mesh or filter fabric required in the drainage swales.

3.3 Architectural Design

3.3 Architectural Design

I. Basis of Design

Architectural aspects of the project relate to the planning of a building structure. The Treatment Building will be a pre-engineered building to contain the miscellaneous equipment.

It will be a rigid frame metal-sided, earth-tone painted structure on a concrete slab with an overhead door for equipment access, a service entry door and an emergency exit door. The footprint will be nominally 76 feet long and 32 feet wide yielding a gross area of 2,432 square feet. The inside wall clear height will be 15 feet. The roof will be metal with gutters and downspouts.

The building size was dictated by the equipment space requirements based on commonly available package treatment units with a reserve factor applied.

The building will have a bathroom with a water closet and lavatory and enclosed office/lab area. The building will be insulated (U-Valve = 0.05) and have heating, ventilation, lighting and fire alarms. An aboveground 1,000 gallon heating oil tank with 110% containment dike will be installed outside of the building. Handicapped access is not required per NAVFAC guidance.

II. Calculations

Appropriate calculations are contained elsewhere or are the responsibility of the building supplier.

3.4 Structural Engineering Design

3.4 Structural Engineering Design

I. Basis of Design

Structural engineering design aspects of the project include reinforced concrete and building structure design. A soils investigation has been performed to determine the allowable soil bearing capacity. A data summary from the soils testing is contained in Appendix A. With a rigid frame, pre-engineered building, it is the responsibility of the supplier to provide the design of the building and footings with all load transferred to the columns.

Between the column foundations, a reinforced concrete frost wall foundation will be constructed and a reinforced concrete slab-on-grade floor poured. Concrete slab design under water treatment equipment will be based on actual working loads for the specific equipment. At a minimum, the floor slab will be designed for a load of 500 psf. The structure will be designed for Seismic Zone 2 conditions.

3.5.1 Heating and Ventilation Design

I. Basis of Design

A heating and ventilating system has been designed for the Treatment Building on a preliminary basis. When the treatment building location and process has been approved and final equipment layout determined, the heating and ventilating system will be finalized.

Oil fired forced hot air has been selected for heating because of the excessive distance (700 feet ±) to connect to the natural gas line at the Firefighting Training Center.

3.5.2 Plumbing Design

I. Basis of Design

Plumbing facilities in the Treatment Building are minor in scope to serve sanitary and emergency functions. An enclosed bathroom with a water closet and lavatory will be provided with a wash sink and emergency shower/eye wash station located in the open work area.

Wash hose facilities will be provided around the treatment units for required cleaning and maintenance.

A point of use (on demand) electric water heater will be designed for domestic use. A separate on-demand electric water heater will be required to temper water temperature to the emergency shower/eye wash station.

Water service pipe to the building will be Type K flexible copper sized to yield 35 psi minimum working pressure. Type L copper pipe will be used for water service in the building sized to provide a maximum flow rate of 10 fps.

Waste piping will be schedule 40 DWV PVC pipe with a minimum size of 3" and slope of 1/4 inch per foot. A separate floor drain/spill containment system will be constructed with 4" schedule 40 DWV PVC pipe to a building sump. A manually activated pump will discharge sump water to the inlet of the treatment system.

Roof drainage flow standards will be established and the gutter design will be the responsibility of the pre-engineered metal building supplier's engineer. A minimum gutter width will be specified.

All designs are based on standard professional engineering practice using the following manuals and codes:

Navfac Design Manual DM 3.01 "Plumbing Systems"
National Standard Plumbing Code

3.5.3 Ground Water Treatment Process Design

I. Basis of Design

Per the Record of Decision, the selected Interim Remedial Action for ground water treatment includes: the removal of dissolved metals using a coagulation/filtration process to meet discharge standards and so that metals do not interfere with subsequent treatment; the removal of volatile organic compounds using a ultraviolet light oxidation system (with polishing using a granular activated carbon adsorption media); and, the discharge of treated water to the Newport POTW via the NETC sanitary sewer system.

The major components of the treatment system have been selected. Final refinement of such aspects as chemical feed rates, UV/oxidation residence time, etc. will be based on bench scale or jar tests to be conducted of the contaminated ground water plume. Valves, sensors, instrumentation and controls are described below and have been shown on Drawings M4 and M5. The predicted maximum ground water extraction flow rate is 25± gallons per minute (gpm) and the treatment system capacity is 50 gpm. This treatment system may be utilized to remediate ground water from other areas of the tank farms in the future.

Designs are based on standard professional engineering practice and criteria from the Navy Design Manuals and Handbooks, American Society of Civil Engineers, Water Environment Federation, the New England Interstate Water Pollution Control Commission (NEIWPCC), etc. The following references have been used for design:

- Navy MH 1005/9, Industrial and Oily Wastewater Control, ©1988
- Water Treatment Principles & Design, ©1985, J.M. Montgomery Consulting Engineers, Inc.
- Guides for the Design of Wastewater Treatment Works, ©1980, NEIWPCC
- American Water Works Association Standards

IA. Treatment Process and Controls Description

1. General

Due to the variability in the ground water extraction well yield as influent to the treatment system, the main process line pump system has been designed for duplex service. With this flexibility, if the total well yield is less than the treatment system design capacity of 50 gpm, one pump may be taken out of service and a lower but steady flow maintained through the process. This is the preferred alternative to cycling the treatment system by batching 50 gpm when the equalization tank fills. In all cases, level controls can automatically activate the second pump to duty based on rising water levels in any of the tanks. The entire system will be integrated with a programmable logic controller (PLC) to sense and operate individual unit processes as well as interlock all units if a failure condition is detected to shutdown all systems.

2. Main Line Process

a. Ground Water Extraction

Ground water will be pumped from wells designed to provide complete capture of the plume. A low level sensor in the wells will turn off the submersible pumps if excessive drawdown occurs to protect against motor burnout. A high level sensor will restart the pump upon recovery. A minimum drawdown in the wells will be established with the sensors so that a gradient exists towards the wells even when the pumps are off to ensure capture.

Extracted ground water will enter the treatment system in an equalization tank (Tank #1) acting to dampen flow surges and prime the transfer pump system. In the tank a probe will measure pH and adjust the caustic feed rate to produce a pH of ±8.5. In the tank feed line a flow indicator (FI) will only allow caustic to be fed in the line when water flow is detected. A mixer

in the equalization tank will be operated on a timed control. At the higher pH the solubility of the metal ions is decreased and precipitates will start to form.

b. Flocculator/Clarifier

As the water level in the equalization tank rises, a pressure transducer will activate one of the transfer pumps (P-OlA) to initiate flow to the flocculator/clarifier (F/C). In the pump discharge line a flow meter (FM) will sense and measure flow to pace the coagulant, flocculant and oxidant chemical feed pumps for injection into this line. If the water level keeps rising in the equalization tank, the transducer/PLC will activate the second transfer pump (P-OlB). If the water level rises further to an unsafe level, the transducer/PLC will shutdown all upstream feed sources (in this case the only upstream feed source is the extraction wells) and activate an alarm in the building and to the Naval Base Fire/Emergency Station. This control logic is repeated in all tank/pump units in the system.

Flow will enter the rapid mixing and flocculation basins of the F/C where mechanical mixers activated by the flow meter provide turbulent and laminar agitation, respectively. The cationic coagulant enhances the formation of the precipitates into particles and the anionic flocculant promotes agglomeration of particles into a larger, settleable mass. The oxidant serves to break down any chelated metals complexed with organics that would otherwise be difficult to settle. The feed rates of all chemicals will be optimized during system start-up based on jar and on-line tests. In the clarifier, flow is directed up through the inclined settling plates to overflow weirs. Solids settle to the hopper bottom for blowoff. Clarified water will overflow to a clearwell (Tank #2). A 90% removal efficiency of Total Suspended Solids can be expected in the F/C to a level of 10 mg/1.

c. Pressure Filtration

F-Red

When the water level rises in the clearwell, a transducer/PLC will activate the transfer pump system (P-02A/B) to charge the water to 25 psi± necessary for the pressure filters. Flow is forced through the dual media (antracite/sand) filters where further solids removal occurs by retaining particles in the pore spaces of the media. Under clean conditions the headloss through the units will be ±4 psi. As solids clog the media, the headloss will increase. The plant operator will manually initiate the backwashing of one filter unit at a time when the headloss approaches ±12 psi. It is expected that with proper operation of the clarifier, the filters will not clog rapidly thus enabling the operator to backwash one unit per day as a good housekeeping practice before they reach the 12 psi headloss while keeping the other unit on-line. If the headloss builds unchecked to the point that the pumps cannot overcome the head required, a pressure switch will activate the shutdown/alarm control. Effluent from the pressure filters should have a Total Suspended Solids concentration below 2 mg/l.

From the pressure filter flow will enter a clearwell (Tank #3) which in addition to priming the next set of transfer pumps will also be used to store water for filter backwashing. Under normal system operation only the top 500 gallons in the tank will be used for the downstream transfer pumps (P-03A/B) as controlled by the transducer/PLC. For backwash water 1500 gallons will remain in the tank for prime on the backwash pump (P-04). In this tank a probe will measure pH and adjust the acid feed rate to produce a pH of ±5.7 using similar controls as discussed earlier for the caustic feed system. This lower pH is required for the UV/oxidation treatment because of possible fouling problems from the carbonate hardness at the higher pH. The tank will be equipped with a mixer operated by an adjustable timer.

d. UV/Oxidation Chamber

The transfer pumps (P-03A/B) will energize the water to a discharge pressure of 15 psi required to move water through the remaining treatment units. A pressure switch on the pump discharge line will sense high backpressure indicating a blockage and initiate the shutdown/alarm sequence. In the UV/Oxidation Chamber, hydrogen peroxide is added as an oxidant and the volatile organic compounds (VOC) in the water are attacked and converted to carbon dioxide, water and inorganic ions. A VOC removal efficiency of 80% can be expected.

e. Granular Activated Carbon Adsorption

Flow then will enter the granular activated carbon filters where remaining organic concentrations are reduced through adsorption to the media. The carbon usage rate should be low because most organics will be removed in the UV/Oxidation Chamber. The effluent will be monitored to determine when breakthrough is approaching.

The treated water will then flow by gravity to the sanitary sewer system for discharge.

3. Off-Line Processes

a. Filter Backwash

The operator will manually operate the valve to initiate backwashing. The backwash pump (P-04) will force water at a high flow rate upwards through the filter to remove solids. The backwash water will enter the Sludge Thickener Tank (Tank #5) to remove solids from the system. Water will be continuously decanted off the top of the tank to the Recycle Tank (Tank #6) while sludge settles to the cone-shaped bottom. High level in this tank as sensed by a float will shutdown any tank feed sources and activate the alarm condition.

b. Clarifier Sludge Blow-Off

Sludge accumulated in the bottom of the clarifier will be intermittently withdrawn by the use of a sludge pump (SP-01) controlled with an adjustable timer. The sludge will enter the Sludge Thickener Tank (Tank #5) at a solids concentration of 1-2%. Water will be continuously decanted from the tank as discussed above. When the Recycle Tank fills, a transducer/PLC will activate a pump to return this water to the head of the treatment plant (Tank #1).

c. Filter Press Operation

As the sludge level builds in the thickener tank (Tank #5), the plant operator will have to manually initiate the filter press operation. Sludge will be withdrawn from Tank #5 using an air diaphragm sludge pump (SP-02) at a solids concentration of 3%± to be dewatered to a cake form with a solids concentration of 30%± for disposal. In the plate and frame type filter press, the system is energized to 100 psi and liquid filtrate is removed from the sludge. The filtrate will flow by gravity to the Recycle Tank (Tank #6) for return to the system. The filter press will be elevated to facilitate this arrangement. The recycle tank will be maintained normally empty (a maximum of 200 gallons to prime the recycle pump (P-05) for this purpose and to ready the process for storage of the 1500 gallon± slug of water resulting from filter backwash. The elevated filter press will also allow the cake to be dropped from the press into drums for storage.

d. Plant Floor Drain System

The building floor slab will be sloped to floor drains which will be piped to a closed sump and pump system. Under normal operation, the floor drains will collect plant washdown water and the pump can discharge these flows to the head of the system (Tank #1). To protect against a chemical spill upsetting this operation, the sump pump (VP-O1) will only be activated by the

operator manually turning the pump on. A float control set at a sump volume of 200 gallons will trip a building alarm telling the operator the sump is filling. The operator can then decide to turn the pump on to discharge the water to Tank #1 or initiate spill containment measures in the sump. If the liquid level continues for rise further, a level control will trip a second alarm to the Naval Base Fire/Emergency Station and shutdown all systems.

e. Treatment System Maintenance Features

Each treatment unit will be equipped with bypass piping to take that system out of service while possibly maintaining plant flow. This operation should only be allowed in an emergency and if the effluent will still meet discharge requirements. The piping system will be installed with line drains/sample taps (L.D.) that will enable equipment and tanks to be drained if necessary. These line drains will be equipped with quick-connect end fittings to allow connection of a portable hose that could be routed to the floor drain or some other removal option.

CHK'D.	REV 4 MAY 1993			

SUBJECT a. Inorganies Treatment

Flow from the extraction wells will enter an equalization tank in the Treatment Building. Caustic chemical (probably Sodium Hydroxide, Na OH) will be added in the water stream prior to the tank to raise the pH to 8.5 ±

The equalization tank is designed to have a minimum residence time, 0 = 30 min. The required volume is then;

Hol = Q × 0 = 50gpn × 30min = 1500gal

Level sensors in the tank will activate a transfer pump that will lift the process water to the inlet of the flocculator/clarifier. In this line polymers and an oxidizing agent will be added as vecessary to facilitate precipitation of metals as hydroxides. The duplex transfer pumps will be sized to pump 1.2 times the expected flow or (1.2×50gm) or 30 gpm each The pumping head is the result of static lift requirements and pipe line friction losses. In the 2" pipe the equivalent length is 150 feet resulting in a dynamic head loss = 8 ft. The static head = 12 ft producing 2 TDH = 20 ft

The pump horsepower can be estimated

The pump horsepower can be estimated (assuming pump efficiency = 55%, motor efficiency = 85%)

 $HP = Q \times H \sim \frac{30 gpm \times 20'}{3960 \times e_{p} \times e_{m}} \approx \frac{30 gpm \times 20'}{3960 \times 0.55 \times 0.85} = 0.33$

Duplex 0.5. horsepower pumps should be used Flow will be throttled to 50 gpm and the pipe size = 2"

BUBJECT a. Inorganics Treatment

In the flocculator the chemicals are mixed with the ground water and precipitates begin to form. Flow then moves up through the clarifier to the overflow weirs, Settleable solids fall and are collected on the clarifier bottom until they are pumped to a studge holding tank. The clarifier is typically sized for a capacity of 0.65 gpm/ft2 thereby requiring an upflow clarifier with an area of 77 ft?

The flow will then enter a charwell storage tank of 500 gallons used to prime the transfer pump necessary to raise the water pressure to 25 ps; for the pressure filters. The transfer pumps will be designed for 30 gpm as before but the TDH = 85 '± The pump horse power required:

HP = 30 gpm x 85 3960 x 0.55 x 0.85 = 1.4

Duplex 1.5 horsepower pumps should be used

The pressure filters are designed for a normal filter rate of 2.5 gpm/H2. The filter area required is them:

50 gpm = 20 ft2 2.5 gpm/ft2

Duplex 3.5 ft & filters will be used so that all flow can be run through one filter when the other requires backwashing. When the headloss through the filter increases to 12 psi t above

TRC TRC Environmental Corporation

PROJECT NO.		
DATE_	20 JAN 1993	
BY	R. Nault	
	REVAMAY 1993	

SUBJECT a. Inorganics Treatment

normal, water at a high vate is forced up through the filter in reverse flow to remove any solids from the filter bed and flush the system. Typical backwash vates range from 10-20 gpm /ft2 for a duration of 10 min. Using an average, the backwash pump vate and sludge thickener storage tank are (for one filter):

Bochwash Rade = 15 ppn x 10 ft = 150 ppm

Tank Vol = 150 gpm x 10 min = 1500 gal.

Backwash Pump size

The backwash water will be recycled to the sludge tank to remove solids. Water leaving the filters will flow into a storage tank required to supply the water to backwash with (Tank reserve volume = 1500 pal). The total tank volume will be 2000 pal. to also prime a transfer pump required to raise the hydraulic grade sufficiently for the organics treatment system. Flow entering the UV oxidation chamber cannot exceed 15 psi. The duplex transfer pumps sizes are then:

HP= 30 gpm × 55' = 0.9 HP & 1.0 HP 3960 × 0.55 × 0.85

TRC Environmental Corporation

Sheet NO OF	
PROJEC	OT NO
DATE _	21 JAN 1993
3Y	
CHK'D -	REV 4 MAY 1993

SUBJECT a. Inorganics Treatment

Off-Line Equipment

Studge generated during the treatment process will be collected in the clarifier. A studge pump will carry studge from the clarifier to a studge storage tank. From the studge storage tank liquids and solids will be batched to a filter press to dewater and reduce the volume to be disposed of. The studge storage tank has been sized so that the filter press has to be run two times per day. The studge leaving the clarifier is only 1-290 solids. Based on a total removal loading of 300 ppm (200 ppm Suspend Solids and 100 ppm metals), the predicted studge generation rate is:

300 ppm x 1 1b/gal x 50 gal x 1440 min = 180 lb day weight

The studge from the clarifier at 2% solids will have a volume of: $180 \frac{16}{day} \times \frac{454}{116} \times \frac{1}{209} \times \frac{1}{3.785} \times \frac{1$

The filter calce volume after pressing to 30% solids would be: 180.16 × 1 × 1913 = 7.5 ft3/day

A filter press of 4 ft3 has been selected requiring two press runs per day at maximum flow and loading. This would fill one 55 gallon drum per day for disposal. (Note that the above analysis is based on the high suspended solids results from previous monitoring. Proper well installation and development may reduce the suspended solids loading which could significantly reduce sludge generation)

Off - Line Equipment

The sludge thickener tank will also receive flow from the clarifier bottom blow-off sludge pump operated on a timer basis. The operation will be adjusted to actual field conditions but will be designed to handle 25 gpm with a specific growity of 1.1. The pump size is then:

 $HP = \frac{25 \, \text{gpm} \times 30' \times 1.1}{3960 \times 0.55 \times 0.85} = 0.44 \approx 0.5 \, \text{HP}$

The sludge thickener tank will have a continuous decant off the top but has been sized to handle the backwash slug of water plus the clarifier blow-off yielding a tank size of zooo gallons for filter press storage. The recycle tank will be maintained near empty with only zoo gallons to prime the recycle pump. The tank volume will be 1500 gallons for storage of the backwash slug of water. The recycle pump will be designed for 25 gpm and the size is then:

HP= 25 9pm x 30' = 0.41 = 0.5 HP 3960 x 0.55 x 0.85

The air diaphragm sludge pump for the filter press will pump 20 gpm at a pressure of 100 ps; requiring 15 SCFM of compressed air.

The building sump will primp 20 gpm and the size is:

 $HP = \frac{20 \text{ gpm} \times 20'}{3 \times 0 \times 0.55 \times 0.85} = 0.22 = 0.25 HP$

SUBJECT a. Inorganies Treatment

Chemical Feed Systems

Caustic (Sodium Hydroxide) will be added neat at 50% concentration liquid form to raise the PH in response to the probe in the equalization tank. The caustic feed system will be provided with a pump capacity of 2.5 gallons per hour (9ph) to be injected with a quill in the tank feed line.

The cationic coagulant, anionic floculant and hydrogen peroxide as an oxidant will be paced into the pump discharge line feeding the floculator / clarifier. The coagulant and floculant come as a liquid or emploion and must be made down to 1:100 dilution. The maximum concentration expected is 5 mg/l. The feed rate is then:

72,000 gal/day x 5 ppm = 0.36 gal/day neat polymer

The diluted feed rate = 0.36 gal/day x 100 = 1.5 gph

24hr/day

The systems will be provided with a pump capacity of 2.5 gph

Sulfuric acid will be added neat at 66° Barne (93% concentration) to lower the pH in response to the probe in the clear well tank. The acid feed system will be provided with a pump capacity of 2.5 gallons per hour to be injected with a guill in the tank feed line.

Hydrogen peroxide feed for the UN/oxidation system is expected at a rate of 6-10 ppd to be injected as part of the oxidation process.

CHK'D	REV 4 MAY 1993

SUBJECT b. Organics Treatment

Flow from the pressure filters will enter the UV/oxidation chamber. An oxidizing agent is added (typically hydrogen peroxide, HzOz) and hydrogxl vadicals are formed to treat the organic contaminants under high intensity UV light. Organic destruction is primarily a function of the individual chemical bonding structure, hydraulic residence time and light intensity. Discussion with vendors indicated that a 30 kilomatt unit would be required with a residence time of 1 minute ±. This will be optomized with a bench scale treatability test.

The rate of UV/oxidation differs with individual organics as discussed earlier. Instead of overdesigning the UV system for one or two contaminants requiring a longer residence time or increased light intensity, a carbon absorption system will be used as a polishing step. Typically, a granular activited carbon tank is sized for a loading rate of 2.5 ppn/ft² and a contact time of 7.5 min. This requires an area of:

GAC = 50 ppm = 20 ft2 2.5 ppm/ft2

A single 5'\$ x 7' high unit has been selected as the system nears breakthrough as evidenced by monitoring, an exchange unit can be ordered. Upon delivery, the units are equipped with quick-connect fittings for fast change-out and little down time.

SHEET	NO 8 OF _ 11
PROJE	CT NO
DATE_	21 JAN 1993
BY	R Nault
CHK'D	REV 4 MAY 1993

BUBJECT b. Organies Treatment

The rate of carbon useage varies with the individual contaminant, but is expected to be low in this application. The UV/oxidation process will destroy most of the organic loading with GAC acting as a factor of safety.

TYPICAL FLOCCULATOR/CLARIFIER

PERMUTIT® PRESSURE FILTERS

Filters are used to remove suspended impurities from water. Prior coagulation is almost invariably necessary. If the turbidity is very low and color removal is not involved, coagulation without settling may be employed. Where raw water turbidity is high or color removal is required, coagulation plus settling should precede the filters, using clarifying equipment such as the Permutit Precipitator, Permujet, or floc-formers and settling basins. Among the most common impurities thus removed are dirt, turbidity, iron, oil and color. Filters with an adsorptive medium are used to remove bad taste and odor. Where water is softened, by either the hot or cold lime soda process, filters are employed to further clarify the water. Neutralite filters can be used on low pH water to raise the pH to approximately 7.1.

A pressure filter is a closed cylindrical steel shell containing a bed of granular filter medium over a collector system. The water to be filtered enters above the bed, percolates downwardly through the filter bed and is drawn off through the collector system at the bottom. Periodically this flow is reversed and the filter is backwashed to carry away the dirt which accumulates on the filter bed. Permutit pressure filters are designed in both vertical and horizontal tank types with straight heights and lengths variable to meet specific requirements. Rotary surface washers or air scour are optional for all types.

Pressure filters are used where the raw or coagulated water is supplied under pressure. Since the effluent from these filters is also under pressure, the necessity of repumping to the point of service is eliminated. They are lower in cost than gravity operated type filters of the same capacity.

2

The Permutit Co., Inc. 1976 Reg. T.M. U.S. Pat. & T.M. Off.

Addition of the Permutit Air Scour feature and careful selection of filter media in Permutit standard vertical or horizontal pressure filters makes them suitable for the reduction of high levels of suspended solids in raw water supplies or in the final filtration of secondary clarified waste waters. The scouring action of air and water achieved by Permutit's Air Scour design loosens sticky, suspended solids which are then washed out with a following conventional water backwash. Permutit Air Scour also reduces wash water volumes. Permutit R. & D. Facilities for bench test or pilot plant test work on the water or waste stream at the job permits selection of the best combination of filter media to suit the application.

1500 lbs. 2000 lbs.

The perox-pure™ chemical oxidation system consists of modular, skid-mounted equipment designed to treat water contaminated by dissolved organic compounds. Bench-scale process evaluations will determine pretreatment requirements (if any) and the oxidation time necessary for the desired treatment level. Full-scale oxidation chamber volume, UV requirements and oxidant dosage are then selected.

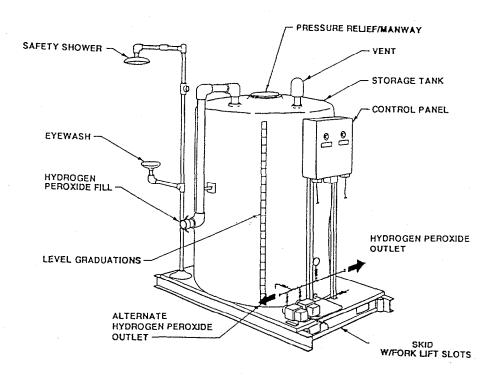

Shipping:

Operating:

The perox-pure™ system incorporates corrosion resistant fluorocarbon-lined oxidation chambers and horizontally mounted medium pressure UV lamps. Indicators are provided to monitor performance of each lamp. A sequential hydrogen peroxide addition feature provides easy process optimization for maximum economy. In addition, a patented tube cleaning device maximizes performance and minimizes maintenance time. The cleaning device is automatic and self propelled, requiring no external actuating mechanism or sliding shaft seals. Other design features include shop-wired and tested control panels interlocked with personnel and process safety features to shut-off power and display the cause at preset conditions. Installation is quick and easy.

The perox-pure™ system and its components are covered by numerous issued and pending patents.

CYCLESORB SERVICESM

CARBON TREATMENT AND SPENT CARBON RETURN SERVICE

The Calgon Carbon Cyclesorb Adsorption Service is provided to offer users of small amounts of granular activated carbon the convenience of both having an easy-to-use adsorber and the capability to return the spent carbon for safe handling by reactivation. Cyclesorb utilizes adsorption with granular activated carbon, a proven and widely used treatment technology, for removal of dissolved organic contaminants from water and wastewater. The Cyclesorb Service is well suited for moderate flows of limited duration such as pump tests, groundwater treatment and intermittent wastewater sources, or treating finite amounts of contaminated water from spills, lagoons or storage tanks.

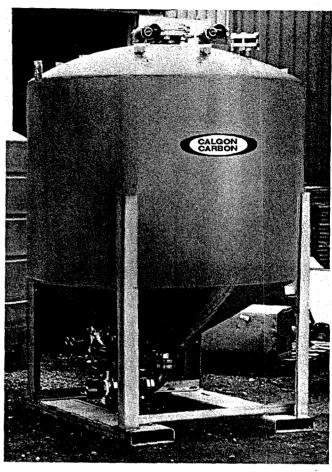

Your Calgon Carbon Technical Sales Representative can help you evaluate the suitability of the Cyclesorb Service to meet your treatment requirements. If needed, adsorption evaluation tests to determine applicability and economics can be arranged. Calgon Carbon offers adsorption equipment in many other sizes, and carbon supply and reactivation exchange services to meet your particular needs.

THE CYCLESORB ADSORBER

The adsorber is a non-pressure unit, constructed of type 316 stainless steel and EPR gaskets. The adsorber is designed to contain up to 2,000 pounds of a selected grade of Calgon Carbon granular activated carbon.

The adsorber, weighing 5,600 pounds for shipping and handling and 7,400 pounds in operation, can be transported via forklift and set on a level area for operation. The unit is 5 ft. in diameter with an overall height of 7 ft. 3 inches. The influent and effluent connections are conveniently made with 2" Kamlock hose connections. The untreated water, at flows up to 60 gpm, enters the top of the unit, flows down through the carbon bed, is collected by a screened outlet and exits the side of the coned section. Sample taps are provided on the influent and effluent connections.

The proper flow through the Cyclesorb is determined by the necessary contact time for the treatment process. The Cyclesorb Adsorbers can be arranged in parallel for increased flows, or in series to take advantage of closer to optimum carbon usage.

The adsorbers are not to be operated above 15 psig, and a rupture disk is included to assure that this pressure is not exceeded.

THE ADSORPTION SERVICE

The user of the adsorption service has the convenience of using the Cyclesorb Adsorber for treatment, and then using the unit as a shipment container to return the spent carbon to Calgon Carbon.

The spent carbon can be returned to Calgon Carbon if it is accepted for thermal reactivation. An acceptability test is conducted on a small carbon sample supplied with the initial Cyclesorb Adsorber, exposed to the water or waste water to simulate spent carbon characteristics. The Calgon Carbon Technical Sales Representative can provide additional information on acceptance of spent carbons.

If the spent GAC has been tested and accepted by Calgon Carbon, the Cyclesorb can be returned to Calgon Carbon, after the spent Cyclesorb is drained of free water. Upon return, the spent GAC will be removed from the unit and thermally reactivated.

If further on-site treatment is required, the spent Cyclesorb can be replaced with a fresh Cyclesorb, with the simple hose connections utilized to switch units.

SPECIFICATIONS

Adsorber Diameter	5 ft.
Unit Height	7 ft. 3 in.
Material of Construction	Type 316 Stainless Steel
Gasket Material	EPR
Operating Pressure/Relief	15 psig (no vacuum)
Hose Connections	2" Kamlock (process)
	½" FNPT (sample)

Flow Rate	0-60 gpm
Weight	Empty-1,040 lbs.
	Filled Dry-3,035 lbs.
	Operating-7,400 lbs.
Ma	x Return (Drained)-5,600 lbs.

CAUTION

Wet activated carbon preferentially removes oxygen from the air. In closed or partially closed containers and vessels, oxygen depletion may reach hazardous levels. If workers are to enter a vessel containing carbon, appropriate sampling and work procedures for potentially low-oxygen spaces should be followed, including all applicable Federal and State requirements.

For information regarding human and environmental exposure, call (412) 787-6700 and request to speak to Regulatory and Trade Affairs.

Calgon Carbon Corporation reserves the right to change specifications without notice for components of equal quality.

For additional information, contact Calgon Carbon Corporation, Box 717, Pittsburgh, PA 15230-0717 Phone (412) 787-6700.

Filter

TYPICAL FILTER

EXCELLENT QUALITY • LOW PRICES •

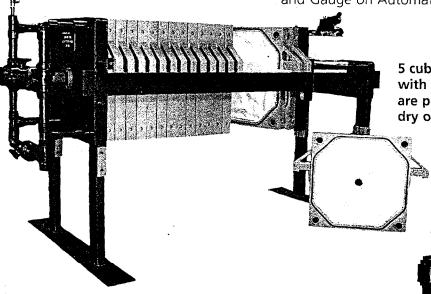

Met-Chem Filter Presses feature heavy duty steel construction with polypro gasketed plates. Presses can be manufactured with manual or automatic closures, but always with a hydraulic cylinder for sure, high pressure closing. Met-Chem's filter presses are always expandable for larger future capacity.

STANDARD FEATURES:

- Air Driven Hydraulic Closing Pump with Pressure Gauge on Automatic Units
- 2 Stage Hand Pump on Manual Units
- Heavy Duty Hydraulic Cylinder for Opening and Closing of Press
- Polypro Gasketed Recessed Plates for Leak Free Operation
- Air Blow Down Manifold Piping for Air Drying Filter Cakes
- Air Line Filter, Oiler, Regulator, and Gauge on Automatic Units

OPTIONAL FEATURES:

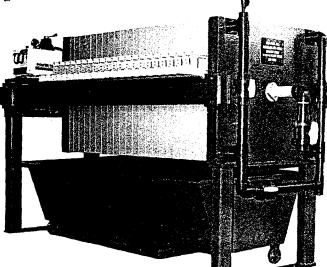

- Sludge Dump Carts for Sludge Collecting and Dumping
- Cat-Walk Platform with Raised Legs for Disposal into Drums or Our Sludge Dryer
- Automatic Plate Shifter for Ease of Cleaning
- Distance Piece for Future Expansion
- Leg Mounted Control Panel
- Diaphragm Pump for Solids
 Feed to the Filter Press

5 cubic foot 630mm filter press with automatic closure. Plates are polypro with gaskets for dry operation.

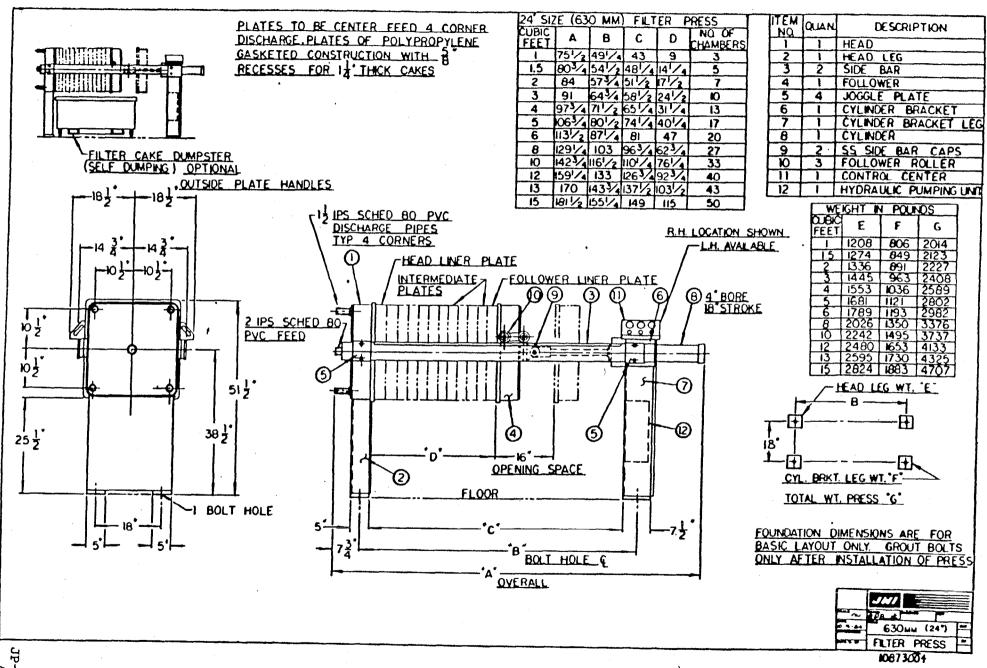

OUR FILTER PRESSES HAVE BEEN USED ON:

- Dewatering Sludges from Industry
- Reclaiming Precious Metals
- Processing of Pharmaceuticals
- Product Filtration
- Dewatering Hazardous Wastes
- Process Waste Waters in EPA Approved Treatment Systems

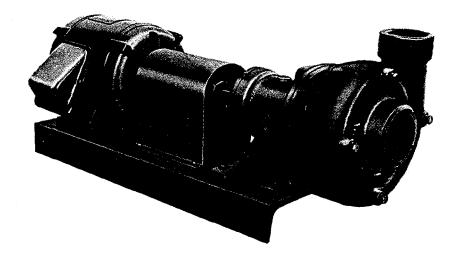

10 cubic foot 800mm filter press with air blow-down manifold piping helps us achieve the driest cake possible. Shown with optional dump cart.

TYPICAL FILTER PRESS

(09/89)

FEATURES

Frame Mounted Design: Flexibility of installation and driver arrangements.

Back Pull-Out Design: Simplifies maintenance when used with spacer type coupling.

Materials of Construction: Available in all iron, bronze fitted or all bronze material for maximum application flexibility.

Replaceable Wearing Components:

- AISI Type 303 stainless steel shaft sleeve.
- · Iron or bronze casing wear ring.

Designed For Maximum
Efficiency: Enclosed impeller design, dynamic balancing and renewable wear rings reduce losses affecting performance and pump life.

Suction and Discharge Pipe Connections: Threaded NPT connections EXCEPT 3 x 4-7 Model only with 125 lb. ANSI flat faced flanges.

Cast Iron Power Frame:

Rigidly supported, grease lubricated ball bearing assembly.

Mechanical Seal: Standard John Crane Type 21 mechanical seal.

Drive Motors: Standard NEMA Design T-Frame motors in 1 or 3 phase.

SPECIFICATIONS

Capacities to:

550 GPM (125 m³/hr) at 3500 RPM 200 GPM (45 m³/hr) at 1750 RPM

Heads to:

280 ft. TDH (85m) at 3500 RPM 67 ft. TDH (20m) at 1750 RPM

Working Pressure: 175 PSIG (12 bars)

Maximum Suction Pressure to: 100 PSIG (7 bars)

Maximum Temperatures to: 212°F (100°C) with standard seal OR

250°F (121°C) with optional high temperature seal for water applications.

Direction Of Rotation: Clockwise when viewed from motor end.

Driver Equipment:

 Motor (Goulds' choice): NEMA standard T-Frame design, 60 Hz. Available as standard selections:

ODP Enclosure-

1 phase—3500 RPM, 3 and 5 HP 1750 RPM, 1-5 HP

3 phase—3500 RPM, 3–10 HP 1750 RPM, 1–5 HP

TEFC Enclosures:

1 phase—3500 RPM, 3 and 5 HP 1750 RPM, 1–5 HP

3 phase-3500 RPM, 3-10 HP

1750 RPM, 1-5 HP

NOTE: Overload protection must be provided. Contactor with overload for single phase and starter with heaters for 3 phase must be ordered separately.

S-Group

- Coupling: T.B. Wood's "SC" Spacer type or equal.
- Baseplate and Coupling Guard: Rigid steel construction in standard unit configurations for 143T through 215T frame motors. For baseplate selections using NEMA T-Frames not shown consult factory.

Motors: OPTIONAL 143T through 215T frame motors are available in ODP or TEFC enclosures. Manufacturer, Goulds' choice. Consult catalog price list for motor availability.

Mechanical Seals: Standard ceramic/carbon faces, 316 SS metal components and Buna-N elastomers. Optional high temperature and severe duty seal materials are available.

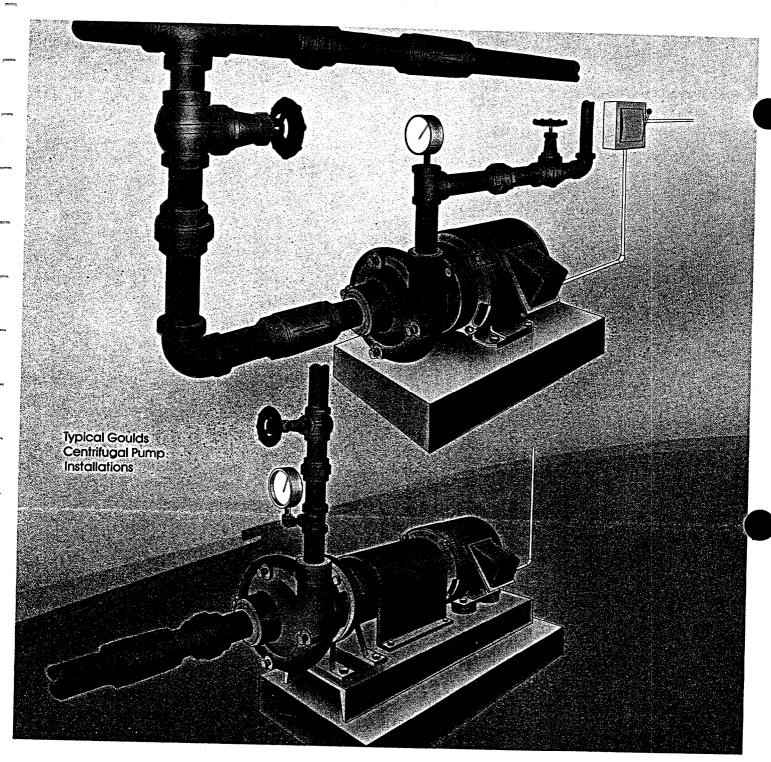

APPLICATIONS

Specifically designed for:

- Water circulation
- Booster service
- Liquid transfer
- Spraying systems
- Irrigation
- General purpose pumping

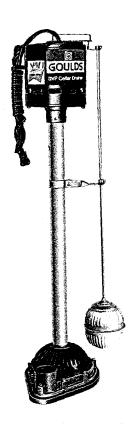

125 lb. Flanged Connections 3 x 4-7 Model Only

TYPICAL TRANSFER PUMP

Goulds Vertical Sump Pumps MODEL

APPLICATIONS

Specifically designed for the following uses:

- Basement draining
- Water transfer
- Dewatering

SPECIFICATIONS

Pump:

- Discharge: 1¼" NPT, will accept adapter for 1½" discharge pipe.
- Power cord: Heavy duty 8 ft., 3-wire cord.
- Temperature: 160°F (71°C) maximum
- Sump diameter: 12 inches or larger

Motor:

- ¼ HP, 115 volt, 60 Hz single phase 1725 RPM with built-in overload protection and automatic reset.
- 6.0 Amps maximum

FEATURES

Top-Side Suction: Positioning of suction strainer in top of casing eliminates impeller clogging from debris in bottom of sump.

Powered for Continuous Operation: All ratings are within the working limits of the motor.

Corrosion Resistant Construction: Plastic semi-open impeller, strainer, base, casing, brass column pipe, stainless steel shaft.

Float Actuated Switch.

EATURES

-Heavy duty fiberglass construction th 3/16" wall thickness (min.). Designed withstand hydrostatic pressure of

120 lbs. per cu. ft.

Available sizes:

- 24" through 72" diameters
- Lengths up to 96 inches

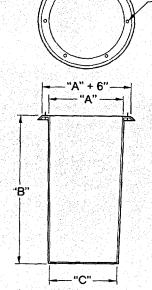

OTE: Contact factory for pricing on nk sizes not listed

Inlet hubs available

*• 4", 6", and 8" cast iron caulking type

• 4" pipe grommet type

Anti-floatation collar provided as standard on basins 78 inches and deeper. Available as an option on basins 36 to 72 inches deep.

6 ea - 34"-16 Tapped metal inserts on "D" bolt circle

NOTE: 18" Basin only have 4 ea. tapped metal inserts

M-2 For Flows to 37 GPM

# WILDEN® MODEL M2®

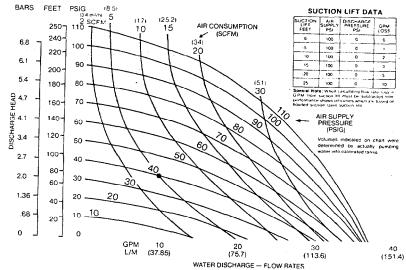

l

Height 101/2"
Width 101/2"
Depth 7"
Weight ALUMINUM 22 lbs.
STAINLESS/HASTELLOY 35 lbs.
Air Inlet ¼" N.P.T.
Inlet 1" Male N.P.T.
Outlet 34" Male N.P.T.
Suction Lift 18' Dry
25' M/ot

Max. Size Solids.. "y" Dia. Example: To pump 10 gpm against a discharge pressure of 35 psig requires 40 psig and 5 scfm air consumption. (See dot on chart.)

Note: For M2 pumps fitted with Teflon diaphragms reduce water discharge figures by 20%. Suction lift for M2 pumps with Teflon diaphragms: 10 ft. dry, 25 ft. wet.

Caution: Do not exceed 125 psig air supply pressure.

1

M-4 For Flows to 73 GPM

# WILDEN® MODEL M4®

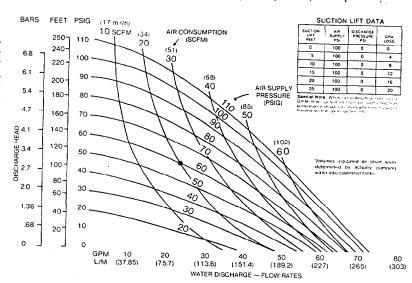

1

Height 18"
Width 141/4"
Depth 113/4"
Weight ALUMINUM 35 lbs.
IRON OR STAINLESS 52 lbs.
Air Inlet 3/4" N.P.T.
Inlet 11/2" Female N.P.T.
Outlet 11/4" Male N.P.T.
Suction Lift 22' Dry
27' Wet
Max. Size Solids., 3/16" Dia.

Example: To pump 22.5 gpm against a discharge pressure head of 45 psig, requires 60 psig and 20 scfm air consumption. (See dot on chart.)

Note: For M4 pumps fitted with Tellon diaphragms reduce water discharge figures by 20%. Suction lift for M4 pumps with Teflon diaphragms: 12 ft. dry. 25 ft. wet.

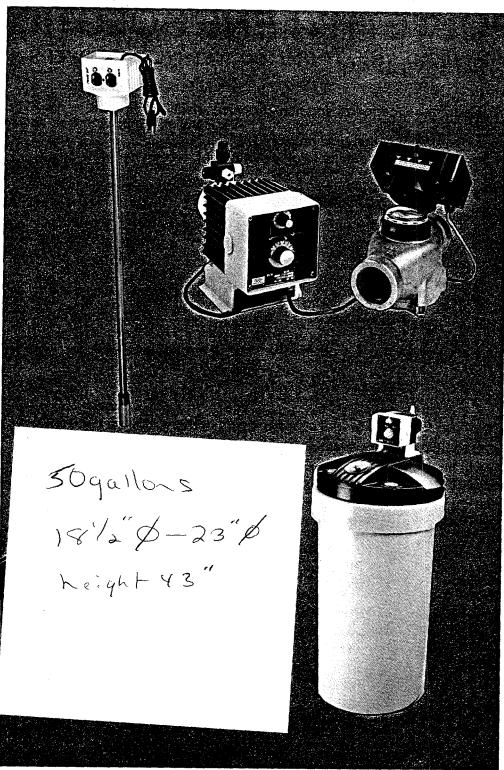

Caution: Do not exceed 125 psig air supply pressure.

# 3.7 Facilities Protection Design

# I. Basis of Design

Freeze

1

rand Tomas With the oxidizing agent stored outside, fire sprinklers will not be required in the building. The "needed fire flow" (NFF) has been estimated according to NFPA and ISO criteria. The existing water supply system is adequate to serve the treatment building fire flow requirements with 20 psi residual pressure.

Inside the building a fire detection system will be installed and wired to the central NETC fire station.

Chain-link fencing will be installed around the building to control entry as discussed in the Civil Engineering Design section of this report.

BY R. Nault

SUBJECT a. Fire Flow Capacity

The Needed Fire Flow (NFF) for the treatment building can be estimated using ISO criteria

Building  $C_i = 18 \times F \times A^{0.5} = 18 \times (0.8) \times (76' \times 32)^{0.5} = 710 \text{ GPM}$ Construction

F=0.8 for Class 3-non combustible (metal)

- Building Occupancy Oi = 1.25 conservative value

Building Xi = 0.08 Nearest building exposure
Exposure Pi = 0

Thus NFF = Ci x Oi x (1+ (X+Pi)

NFF= 750 x 1.25 x 1.08 = 1012 6PM SAY 1000 6PM

From the NETC Water System Flow Test and
Records of Don Wescott NETC Marshall

Water System Flow Test 2/26/93 (see map)

Testing Hydrant Static 59psi Residual 30 psi

Flowing Hydrant 21/24 nozzle 34 psi = 1088 gpm Using a factor of 0.8 say Q= 870gpm

SHEET NO OF			
PROJECT NO			
DATE	30 APR 1993		
	R. Nault		
BY	F. Maoti		
CHYIN			

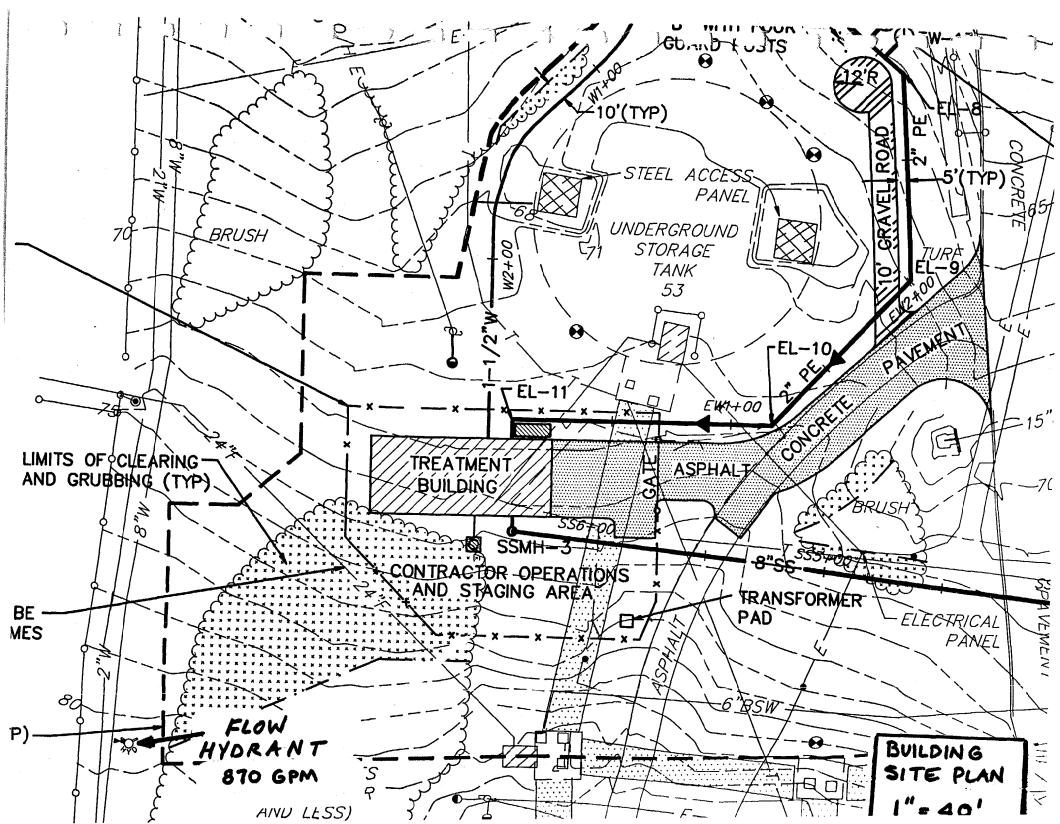

SUBJECT.

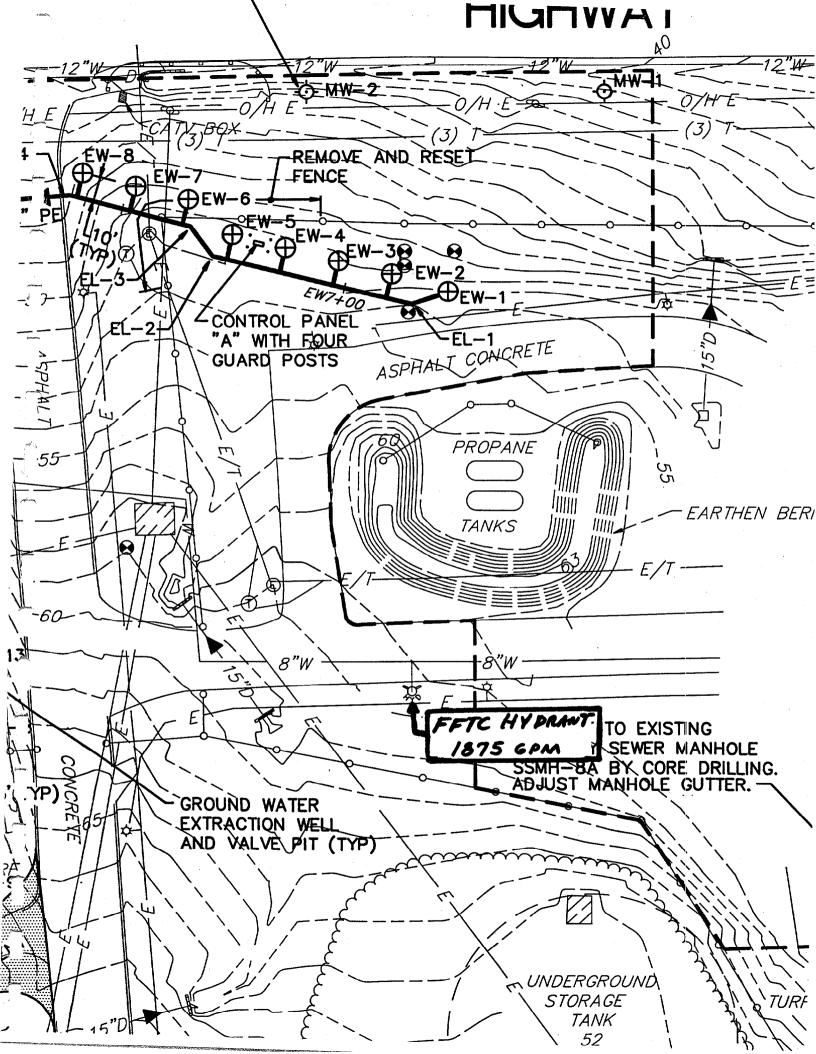

To correct for flow at a residual pressure of 20 psi:

$$Q_{R} = \frac{Q_{r} \times h_{r}^{0.54}}{h_{f}^{0.54}} = \frac{870 \text{ gpm} \times (59-20)^{0.54}}{(59-30)^{0.54}}$$

The fested hydrant is within 300 ft of the treatment building and thus provides full credit of 1000 gpm towards meeting the NFF. In addition, from flow records of 10/26/91 it was found that the hydrant at the FFTC had a capacity of 1875 gpm @ 20 psi. It is between 300-600 ft from the treatment building and produces a credit of 670 gpm. From these records it shows that the NFF of 1000 gpm can be met with the existing water system.

The Design Drawings show the path between the treatment building and the tested hydrant will be cleared to allow easier access in the event of a fire.

# 4.0 GROUND WATER REMEDIATION OPERATION AND MAINTENANCE REQUIREMENTS

# 4.1 Operation and Maintenance - Ground Water Extraction System

The ground water extraction system has been designed to require a minimal amount of maintenance and includes a variety of safeguards which will shut the system down in the event of a serious malfunction. However, the system will require routine checks by the operator at least one time per week and more extensive monitoring and maintenance approximately once a month. Each of the areas of operation for the ground water extraction system are described below.

# 4.1.1 Monitor Ground Water Extraction Rates

At least once per month, the total flow rates in each of the extraction wells should be measured by reading and recording the flow meter in the well valve pit. Water extraction rates will be measured so that well performance and hydraulic conditions in the various portions of the site can be determined.

# 4.1.2 Monitor Ground Water Levels

At least once per month, the water levels in each of the monitoring wells should be measured. These levels will be evaluated to determine if current pumping rates and drawdowns are sufficient to create flow gradients toward the wells throughout the area where ground water contamination exists. Pumping rates and drawdowns will be adjusted, if necessary, by adjusting the flow regulating globe valve in the well valve pit.

# 4.1.3 Monitor Extraction Well and Monitoring Well Water Quality

To detect the possible migration of contaminants, the ground water quality should be monitored. Extraction well water quality will be monitored inside the treatment building as influent to optimize the treatment process. Ground

water samples will be collected on a quarterly basis from the downgradient monitoring wells and analyzed for priority pollutant volatile organic compounds and metals. These results will be used in evaluating the migration of the contaminant plume and capture efficiency of the ground water extraction wells.

# 4.2 Operation and Maintenance - Treatment System

The treatment system has been designed to be as automated as possible with safeguards which will shut the system down in the event of malfunction. This will minimize damage to workers, equipment and the environment. A plant operator will be required to perform manual operations such as adjusting pumping rates, backwashing, operating the filter press, refilling chemical feed equipment, performing chemical analysis, etc.

The treatment system has been designed to require manned operation only one shift per day. Storage tanks and equipment have been selected to accommodate at least one days flow. This operating basis, along with a complete schedule of tasks, will be developed in an Operations and Maintenance Manual for the Treatment System.

# 4.2.1 Monitor Treated Water Quantity and Quality

The influent flow to the treatment building will be measured daily and recorded. Sample ports will be installed between the treatment units for water quality sampling. Daily testing of inorganic contaminants at the following points is feasible with relatively simple spectrophotometers, pH meter, mass balance and other lab equipment:

• Plant influent

Carren

- Clarifier influent
- Filter influent
- Filter effluent
- Plant effluent

Testing should be performed for metals concentration, pH, total suspended solids and hardness. Results should be recorded and analysis performed of treatment efficiencies, adjustments necessary to optimize process performance and conformance with discharge requirements.

Testing and analysis or organic contaminants for priority pollutants will be submitted to a certified laboratory. Samples should be taken at the plant effluent at a frequency consistent with the Newport POTW discharge permit conditions (typically once per month). To compare the UV/oxidation treatment efficiency with the granular activated carbon system, additional samples should be collected at the UV/oxidation influent and effluent at desired intervals (for example, once every three months).

# 4.2.2 Treatment Equipment Operation

The main process line of the treatment train is designed to operate automatically under normal working conditions. The plant operator will have to perform manual functions such as change over of chemical feed supplies and off-line processes such as backwashing and filter press use on an as-needed basis. Treatment equipment operation and maintenance guidelines and requirements will be developed during construction using information on actual equipment installed under this contract.

# 4.2.3 Treatment Equipment Maintenance

A maintenance manual for all equipment is required from the contractor that will detail suggested procedures and frequencies. The treatment process includes mechanical equipment such as pumps, valves, pipe and floats, and electrical equipment such as motors and controls. Personnel trained and experienced with this equipment will be needed to properly maintain this system.

TRC Environmental Corporation

SHEET NO OF			
PROJECT NO. 12773			
DATE 9/22/93			
BY CMI			
OUT			

SUBJECT NETC NEWPORT - TANK FARM 5 IRM

# SOILS REPORT & FOUNDATION ANALYSIS

Four Test Borings were drilled within the footprint of the new treatment building. Each boring penetrated to a depth of approximately 20 feet below the surface. The soils beneath the new building can be generalized as follows:

0'-2' Brown Med. Sand & Grave!

3'- 10" Grey & Brown Grey Loose to Medium Compact Gravelly Sand and Silt

10'- 15' Brown Dense to Very Dense Sand and Sitt with weathered shale fragments

15'-20' Weathered Shale and Quartz

Ground water was not encountered.

Footings for the building will be constructed at a depth of approximately 3'to 9' below the present ground surface. The following is a summary of the blow counts for the standard penetration test at each boring at approximately 3'to 8'

BOEING # B-1 B-2 B-3 B-4

Blow Counts 14 17 12 35
Per Foot (N)

USE A VALUE OF N= 15 FOR DESIGN

**TRC**TRC Environmental Corporation

SUBJECT NETC NEWPORT - TANK FARMS IRM

The boring logs below the 8'depth show a significant increase in blow counts and compactness, therefore the use of N=15 for footing design is ox. The building footings will be two types as follows

- O Continuous footing for frost wall around building. This feeting will have low lead condition since it is a non-bearing support footing. An 18" wide footing will be assumed.
- Square Spread Footings for piers which support the building structural steel fixed frames. These footings typically are on the order of 5 feet square.

# Computation of Allowable Bearing Capacity

#### APPENDIX B

SUMMARY OF FIELD AQUIFER TESTING AND NUMERICAL MODELING

#### APPENDIX B

#### SUMMARY OF FIELD AQUIFER TESTING AND NUMERICAL MODELING CONCEPTUAL REMEDIAL DESIGN - GROUND WATER RESTORATION SITE 13 - TANK FARM FIVE

NAVAL EDUCATION AND TRAINING CENTER, NEWPORT, RHODE ISLAND

#### **INTRODUCTION**

This report summarizes field aquifer testing and numerical computer modeling activities conducted for the purpose of designing an on-site ground water recovery and treatment system for NETC Newport Site 13, Tank Farm Five. These activities have been carried out in accordance with the Remedial Design Work Plan, Ground Water Treatment, Interim Remedial Action (TRC Environmental Corporation (TRC), January 1993), with the purpose of implementing a remedial system which will provide capture and treatment of the Tank Farm Five ground water contaminated at levels over ARARs/TBCs, as determined during the Phase I Remedial Investigation (TRC, November 1991).

#### FIELD AQUIFER TESTING

Aquifer slug tests and pump tests were conducted at the site to obtain weathered/fractured bedrock aquifer hydraulic data such as hydraulic conductivity, transmissivity and specific yield. The pump tests were also used to assess the response of the aquifer, in terms of radius of influence and drawdown, to pumping stresses. The results were then used in the recovery system design to determine the optimal number of extraction wells, well spacing and wellfield configuration for capturing the ground water contamination plume associated with Tank 53 at Tank Farm Five. A secondary goal was to determine the potential long-term sustainable yield from the proposed extraction wellfield. Information on the site-specific geology and hydrogeology is provided in Sections 3.4.2 and 3.5.2 of the Phase I RI Report.

#### Slug Tests

On July 25, 1990, as part of the Phase I RI field investigation, slug tests were performed at on-site monitoring wells, including MW-1S, MW-2S, MW-3S, MW-5S and MW-6S. The slug tests were conducted using a PVC rod as a slug. Prior to inserting the slug test rod into the well, a pressure transducer connected to a digital LCD readout was lowered into the well. The pressure transducer provides a continuous readout of the amount of water (feet) that is above the transducer. Once the water level had equilibrated after the slug test rod was lowered into the well, the slug rod was rapidly removed from the well and the transducer readings were recorded at specified intervals for approximately five minutes. The results of the slug tests, as presented in Appendix J and discussed in Section 3.5 of the Phase I RI Report, indicated a

hydraulic conductivity (K-value) range from 0.16 feet per day (ft/d) (MW-2S) to 0.25 ft/d (MW-6S), with an average K-value of 0.19 ft/d.

#### Pump Tests

100

#### Pumping and Observation Well Installation

From January 6, 1993 to January 12, 1993, for the purpose of conducting a 24-hour aquifer pump test, one pumping well (PW-1) and two observation wells (OW-1 and OW-2) were drilled and installed in the area of Phase I RI monitoring well MW-4 (Figure 1). MW-4 is located 20.5 feet to the northeast of PW-1, OW-1 is located 5.8 feet to the southeast of PW-1, and OW-2 is located 25.1 feet to the southeast of PW-1. OW-1, OW-2 and MW-4 thus form an orthogonal system of monitoring wells around PW-1.

The drilling and well installation activities were performed by the D.L. Maher Company, under the direction of TRC. The well boreholes were advanced using 4¼-inch I.D. hollow-stem augers, which create eight-inch-diameter boreholes. From the MW-4 boring log (Appendix G. Phase I RI Report), it was anticipated that the lithology would consist of an overburden of silt, weathered shale and fine sand to a depth of approximately 16 feet, where weathered shale bedrock would be encountered. The bedrock was expected to become more competent at a depth of approximately 30 feet. During the drilling of the first well installed, OW-1, two-inch splitspoon samples were collected every five feet until spoon refusal at 20.5 feet below grade. The samples indicated overburden materials consisting predominantly of silty fine to medium sand, silt and weathered shale. Weathered shale bedrock was encountered at approximately 15.5 feet, as revealed in the 15- to 17-foot spoon. Upon advancing the augers, bedrock was found to increase in competence at approximately 25 to 30 feet below grade. Auger refusal at OW-1 was encountered at 46.5 feet below grade. PW-1 and OW-2 were subsequently drilled with the 4¹/₄inch I.D. hollow-stem augers, with no split-spoon sampling. The PW-1 and OW-2 boreholes were advanced to the maximum design depth of 50.0 feet below grade with no auger refusal. All boring cuttings were placed in 55-gallon, open-top drums; each of the drums was labeled on its top and side with the site identification, contents and date, and was transported to Site 01, McAllister Point Landfill, for storage.

Upon advancing the augers to the final well depth, each well was constructed by lowering the well, constructed of twenty feet of two-inch I.D., Schedule 40, 20-slot PVC screen connected to a two-inch I.D., Schedule 40 PVC riser, inside the augers to the bottom of the borehole. The riser length was determined so as to provide a riser stickup of approximately two feet. Then, while slowly raising the augers, the annulus surrounding the well was filled with a filter pack consisting of #1 Morie well gravel, to a minimum height of 2.5 feet above the top of the screen. The augers were then completely removed from the borehole and two to three feet of bentonite chips were placed atop the filter pack; the bentonite was hydrated and allowed to swell for 24 hours prior to grouting. A grout mixture of 95% Portland cement and 5% bentonite clay grout was then mixed in a hopper and was tremied into the borehole to a depth

of approximately 2.5 feet below grade. A four-inch steel protective casing, five feet in total length and fitted with a locking cover, was then placed surrounding the riser and cemented into place with Portland cement reinforced with #1 Morie well gravel. Finally, the well identification was painted onto the protective casing. The well boring and construction logs are presented as Attachment A.

After drilling and well installation activities were completed, each of the new wells was developed. At each well, a length of dedicated polyethylene tubing, fitted with a foot check valve, was lowered to the bottom of the well. The tubing was connected to a Waterra inertial lift pump, which utilizes a piston action to bring the well water to the surface, while imparting a moderate surging effect. Each well was developed for two to three hours. Typically, at first the pumped water would be light grey, cloudy and silty; the silt content and degree of cloudiness decreased with time. The approximate average yields ranged from 0.65 gallons per minute (gpm) (OW-2) to 1.0 gpm (OW-1). All wells were pumped dry at least once during their development. The development water was directed into 55-gallon, open-top drums, which were then labeled and transported to McAllister Point Landfill for storage.

#### Pump Tests - General Procedure

Constant-rate pump tests were performed on PW-1 on February 11, 1993 and on March 17-18, 1993. A Grundfos Redi-Flo2 two-inch electric submersible pump was used to pump PW-1. One-half-inch polyethylene tubing was clamped to the flow outlet atop the pump and the pump electric power cord was taped to the tubing, and the pump was lowered to the bottom of PW-1. The tubing emerging from the wellhead was fitted with a gate valve (to prevent return flow down the tubing during recovery), a spigot, and a 5/8-inch totalizing flow meter. Additional tubing was then added as necessary to direct the flow from PW-1 approximately 450 feet southeast to Tank 52, where the tubing was directed into the ventilation shaft of the tank. Power to the pump was provided by a 1500-watt portable generator, through a Grundfos BMI/MP1 pump converter box, where pump speed could be electronically controlled.

After installing the pump, pressure transducers were placed in wells PW-1, OW-1, OW-2 and MW-4, and were connected to an Enviro-Labs EL-200 electronic data logger to provide digital water level readouts and data recording. Depth-to-water measurements were periodically made at each of the four monitored wells, to provide water level elevation correspondence to the height-of-water readings recorded from the transducers. For at least 12 hours prior to the initiation of each pump test, water level measurements were recorded at each well every 15 minutes, for the determination of any trends in the pre-pumping water levels (i.e., upward, downward or fluctuating) that could be incorporated into the pump test data interpretations.

Prior to the initiation of Pump Test 1, a short-duration step-drawdown test was performed on PW-1 on February 10, 1993 to determine the optimal pumping rate for maximizing drawdown without drying the well. The step-drawdown test involves increasing the pumpage from the well in successive steps or stages while recording the changes in water level in the pumped well. An initial pumping rate of 0.5 gpm was selected for the first step; this rate

resulted in approximately 8.5 feet of drawdown in the well, after one hour of pumping. The flow rate was subsequently increased to 0.75 gpm; this rate caused the water level to fall below the transducer, located approximately 2 feet above the pump, after 45 minutes. The flow rate was then reduced to 0.45 gpm, where the water level stabilized at approximately 21 feet of drawdown. From this information, a flow rate of 0.35 gpm was proposed for the pump test.

In preparing for each pump test, the data logger was programmed with a sampling sequence that would allow data to be collected at intervals that would be initially short (i.e., every second) and would gradually lengthen, to a maximum interval of 10 minutes. For the beginning of the recovery period, the logger would be programmed to start a new recording event, to log the recovery data under the same interval schedule as for the pump test.

#### Pump Test 1

On February 9 and 10, 1993, two attempts were made at performing a 24-hour pump test of PW-1. During these two attempts, pump failure and water freezing in the effluent line after the step-drawdown test necessitated postponement of the pump test. On February 11, 1993, a nine-hour pump test of PW-1 was performed, with an average pumping rate of 0.35 gpm. In accordance with the Work Plan, the test was intended to be conducted for 24 hours or until a steady state had been reached. However, it was necessary to terminate the test at nine hours, when a voltage surge caused the pump converter box to shut off current to the pump. When the pump stopped, the water in the effluent line froze in several locations along the line. It was then decided to postpone further testing until weather conditions permitted.

During Pump Test 1, two rounds of effluent samples were collected for laboratory analysis. These samples were collected to provide additional ground water quality information near the leading edge of the contaminant plume and to provide additional information to be used in the treatment system design. The first sample (TF5-PW1-01-021193) was collected approximately 2.5 hours into the pump test, and the second sample (TF5-PW1-02-021193) was collected approximately one half-hour after the test was terminated. The samples were collected at the in-line spigot at the wellhead; water from the spigot was collected directly into the sample jars. Samples were collected for the following analyses:

- Volatile organic compounds (VOCs);
- Base neutral/acid extractables (BNAs);
- Pesticides/PCBs;
- Cyanide;
- Hardness:
- Total dissolved solids (TDS), total suspended solids (TSS), pH and alkalinity; and
- Metals iron and manganese.

The effluent samples were shipped to Weston Analytics in Lionville, Pennsylvania for analysis. The analytical results are presented in Table 1.

In addition to the samples for laboratory analysis, two rounds of effluent samples were collected for field parameter screening. The first sample was collected at approximately 6.5 hours into the pump test, and the second sample was collected approximately one hour after the termination of the test. The samples were measured for temperature, conductivity and pH. The Yellow Springs Instruments Model 33 S-C-T meter was used to measure temperature and conductivity, the Orion Research Ionalyzer Model 407A was used to measure pH, and the Orion Research Portable Meter Model SA230 was used to measure temperature and pH. The field parameter screening results are presented in Table 2.

#### Pump Test 2

On March 17 and 18, a 24-hour pump test was performed, with an average pumping rate of 0.34 gpm. Following completion of the pump test, the pump was shut off and non-pumping, recovery measurements were collected for a three-hour period. The recovery monitoring was terminated after three hours because the water levels in all of the wells had recovered either to or above their original pre-pumping levels, and the water levels were at near-stasis.

#### Pump Test Analyses

The pump test data were analyzed to determine aquifer hydraulic characteristics using AQUIX123™ (Interpex Limited, 1988), an interactive analytical computer program. The analytical method used was the curve-fitting method developed by Neuman (1975) for completely or partially penetrating wells in an anisotropic unconfined aquifer with delayed gravity response.

The background water level measurements taken prior to each of the pump tests did not show a significant pre-pumping trend of upward or downward change in the water level at any of the monitored wells. However, prior to and for approximately the first 10.5 hours of Pump Test 2, a light to heavy rain fell on the site. Snow and freezing rain fell on the site from 10.5 hours until approximately 16.5 hours into the pump test. The effect of precipitation recharge to the ground water was observed both during the late stages of the pump test, where water levels rose despite maintaining a constant 0.34 gpm flow rate, and in the recovery period, where the water levels rebounded to levels up to 0.15 foot (OW-1) above the pre-pumping levels. For the purpose of preparing the data for analysis, a "background" correction factor of 0.15 foot per 24 hours was applied to the Pump Test 2 pumping and recovery data to compensate for the precipitation recharge impact.

As summarized in Table 3 and in Attachment B, the analysis of Pump Test 1 yielded K-values ranging from 0.30 ft/d (OW-1) to 0.77 ft/d (MW-4), for an average K-value of 0.55 ft/d. The Pump Test 2 pumping analysis produced K-values ranging from 0.14 ft/d (OW-1) to 5.95 ft/d (MW-4), for an average K-value of 2.23 ft/d. The Pump Test 2 recovery analysis yielded K-values ranging from 0.18 ft/d (OW-1) to 2.27 ft/d (MW-4), for an average K-value of 1.09 ft/d. The highest K-value was consistently derived from the MW-4 data, followed by OW-2 and OW-1. It is noted that MW-4 is screened from 16 to 31 feet below grade, approximately 20 feet above the other three wells. In addition, MW-4 is located perpendicular to OW-1 and OW-2

with respect to PW-1. These factors may have resulted in differences between MW-4 and the other two observation wells in responding to the pumping at PW-1. After excluding the 2.27 ft/d and 5.95 ft/d MW-4 K-values as high, the average of the remaining K-values determined from the two pump tests was 0.48 ft/d. From this, a K-value of 0.50 ft/d was selected for initial hydraulic parameter input to the remedial design computer model.

#### NUMERICAL COMPUTER MODELING

#### **Objectives**

The estimated area of ground water at Tank Farm Five contaminated at levels in excess of ARARs/TBCs is shown in Figure 2, and is presumed to constitute a plume extending roughly northward from Tank 53 to the MW-4 area. Using the aquifer hydraulic data collected during both the Phase I RI and the subsequent pump tests, numerical computer modeling was conducted for the purpose of designing an on-site ground water pump and treat remedial system that would provide capture and treatment of the contaminated ground water. The goal was to provide capture of ground water both close to the apparent contaminant source at Tank 53, as well as at the presumed downgradient edge of the plume, in the MW-4 area.

#### **Methodology**

#### Model Setup and Initial Input

FLOWPATH™ (Waterloo Hydrogeologic Software, 1992), a two-dimensional numerical ground water flow and pathlines simulation model, was used in the ground water recovery system design. FLOWPATH assumes the following: 1) the pumping wells fully penetrate the model layer, and no water is stored in the well bores; 2) prior to pumping, the regional piezometric surface can be either horizontal or sloping; and 3) water is released instantaneously from storage by the compaction of the aquifer matrix and by the expansion of the water itself. Additionally, it was assumed that the aquifer was a homogeneous, isotropic medium and that steady state conditions were to be simulated.

The model input parameters and results are summarized in Table 4, and the resulting graphical output is presented in Figures 3 through 7. The initial aquifer K-value was set at 0.50 ft/d and the aquifer porosity was set at 0.05 (5%), the average typical value for shale (Freeze and Cherry (1979) and Driscoll (1986)). The average aquifer saturated thickness was set at 30 feet; this represents both the saturated thickness at PW-1, OW-1 and OW-2 during the pump tests, as well as the minimum nonpumping saturated thickness proposed for the recovery wells. The aquifer was modeled as unconfined, where a portion of the water stored in the aquifer is released by dewatering of the aquifer, and transmissivity is a product of the hydraulic conductivity and saturated thickness.

The area encompassed by the model grid is shown in Figure 3. The grid was aligned to parallel the roughly north-south ground water flow direction in the modeled area. The grid measured 600 feet (east-west) by 700 feet (north-south), and was configured with 36 rows and 34 columns with variable nodal spacing.

#### Model Calibration

For initial steady-state (non-stressed) calibration, initial head matrices, determined from the average ground water contours for July 17, 1990 and September 20, 1990 (Figures 1 and 2, Site 13 - Tank Farm Five, Phase I RI Report), were input to the model. The average horizontal hydraulic gradient in the area for these two monitoring events was 0.027 ft/ft. As the modeled area of the aquifer is not known to be bounded on any side by an impermeable hydraulic boundary, constant-head boundaries were placed on the grid surrounding the modeled region to establish flow through the model. After each model run was conducted, the aquifer hydraulic conductivity value and/or the constant head boundary values were adjusted as necessary. Using this technique, a satisfactory calibration was achieved for the average non-pumping ground water contours for July 17, 1990 and September 20, 1990. Figure 4 shows the results of the steady-state calibration process.

#### Model Verification

Following the steady-state calibration, the model was verified to stressed bedrock aquifer conditions imposed by the pumping of PW-1 during Pump Test 2. This process was completed by calibrating the model to the ground water levels observed during the late stage of the pump test at observation wells OW-1 and OW-2. The model verification output is presented in Figure 5. The node representing PW-1 was designated a negative flux boundary, and the model was run under steady-state conditions. The K-value was further adjusted to provide agreement between the modeled contours and the water levels measured at the observation wells during the pump test. The adjusted K-value, 1.0 ft/d, was then input to the steady-state calibration simulation, to verify its suitability to both non-stressed and stressed aquifer conditions.

#### **Extraction Wellfield Simulations**

After completing the model calibration and verification steps, several extraction wellfield configuration options were evaluated with respect to the goal of capturing ground water flow from areas that were found in the Phase I RI to exhibit contamination above ARARs/TBCs. It was assumed that a series of extraction wells would be located in the area of the presumed downgradient edge of the plume, in the MW-4 area. An additional goal was to provide capture of ground water just downgradient from the apparent ground water contamination source at Tank 53, to minimize the potential for future mechanical dispersion and chemical diffusion of contaminants migrating from the tank area with the bulk ground water flow.

For each of the extraction scenarios, numerous evaluations were made to determine the optimum combination of extraction rates and well locations for that scenario. The resultant

ground water hydraulic head distributions and corresponding calculated pathlines and capture zones were inspected to ensure that adequate capture was accomplished across the estimated area of contaminated ground water. Based on the low yield of PW-1, it was assumed that, taking into account well interference effects, the system design would incorporate an average extraction rate of 0.25 gpm (360 gallons per day (gpd)) per well. This was done to ensure that the recovery wellfield would be of sufficient density and areal extent so that capture of the contaminated zone would be accomplished even at this low flow rate.

For the purposes of performing a sensitivity analysis and of simulating the response of the system to the potential presence of zones of higher hydraulic conductivity, the model K-value was raised to 5.0 ft/d. The recovery well extraction rates were then increased until capture of the contaminated ground water was shown. Additional sensitivity analyses were conducted to evaluate the effect on the model output of different values for porosity and aquifer thickness. In general, a higher porosity or a larger aquifer thickness would require higher pumping rates to obtain an adequate capture zone.

An extraction well's zone of influence includes the entire area in which drawdown occurs in response to the ground water sink created by the well. Capture zones are limited to those portions of the flow regime where the water table/piezometric surface can be seen to be sloped toward the extraction well, so that ground water, flowing perpendicular to the piezometric contours, would likely be drawn into the well. Therefore, the extraction well's zone of capture does not include the entire zone of influence for the well.

#### Model Results/Recommended Recovery Wellfield Design

The results of the extraction wellfield modeling indicated that a network of 13 extraction wells, shown in Figure 6, would provide capture of the area of ground water contamination between Tank 53 and the MW-4 area. Eight of these wells would lie in a line stretching southwest from approximately the MW-4 location to the Fire Fighting Training Center entrance road. These wells would have a center-to-center spacing of 22.5 feet, for a total line length of 157.5 feet. The remaining five wells would lie in an east-west line approximately 60 feet downgradient from Tank 53, adjacent to monitoring well MW-8. These wells would have a center-to-center spacing of 10.0 feet, for a total line length of 40.0 feet. The resultant particle pathlines and wellfield capture zones are shown in Figure 7. At its widest point in the modeled area, the capture zone would measure approximately 440 feet across; the downgradient extent of capture would lie approximately 35 feet beyond the downgradient line of recovery wells.

The results of the sensitivity/system analysis indicated that an increase of hydraulic conductivity to 5.0 ft/d would result in a directly proportional increase in the extraction rate necessary to establish adequate capture. Therefore, operating in a saturated medium with a 5.0 ft/d K-value, each well would extract at 1.25 gpm (1,800 gpd), for a total system flow rate of 16.25 gpm (23,400 gpd).

The recovery wells should be designed to provide adequate available drawdown in the event that the wells have to be pumped at higher than the design rate to provide capture. As an additional modeled test of system response to varying pumping stresses, the K-value was entered as 3.0 ft/d and the pumping rate was raised to 2.0 gpm (2,880 gpd) per well (26.0 gpm (37,440 gpd) total). The maximum drawdown measured in this scenario was 20.3 feet. To provide adequate available drawdown in the event that the wells have to be pumped at higher than the design rates, it is recommended that each well be designed to provide a non-pumping water column of 70 feet. This would translate to a design well depth of 100 feet in the downgradient line of wells near MW-4 and a design depth of 110 feet in the upgradient line of wells adjacent to MW-8. Table 5 summarizes the design specifications of the recovery wells proposed for Tank Farm Five.

#### TABLE 4

# FLOWPATH MODEL INPUT PARAMETERS AND RESULTS CONCEPTUAL REMEDIAL DESIGN — GROUND WATER RESTORATION SITE 13 — TANK FARM FIVE NAVAL EDUCATION AND TRAINING CENTER, NEWPORT, RHODE ISLAND

K-VALUE SELECTED FROM AQUIFER HYDRAULIC TEST

ANALYSES FOR INITIAL MODEL INPUT:

0.50 ft/d

NUMERICAL MODEL FOR SIMULATION

OF AQUIFER AND RECOVERY SYSTEM:

FLOWPATH Ver. 4 (Waterloo Hydrogeologic Software, 1992)

Assumptions: Isotropic medium, steady state conditions

INITIAL MODEL INPUT:

 $K = 0.50 \, \text{ft/d}$ 

Aquifer Porosity = 0.05 (Average typical value for shale (Freeze and Cherry, 1979

and Driscoll, 1986))

Aquifer Saturated Thickness = 30 ft

MODEL CALIBRATION:

FIELD DATA:

Average Estimated Water Table Contours, 07/17/90 and 09/20/90

(Figures 1 and 2, Site 13 - Tank Farm Five, Phase I RI Report (TRC, November 1991)

Average Horizontal Hydraulic Gradient = 0.027 ft/ft

MODEL VERIFICATION:

FIELD DATA:

Maximum Compensated Drawdown at observation wells OW-1 and OW-2

PW-1 Pump Test, 03/17/93-03/18/93

**VERIFICATION RESULTS:** 

<3% deviation from actual Maximum Compensated Drawdown at OW-1 and OW-2

Adjusted K = 1.0 ft/d

RECOVERY WELLFIELD SIMULATION

RESULTS AND RECOMMENDED

WELLFIELD DESIGN:

Number of Recovery Wells = 13 (Five just downgradient of Tank 53, Eight in

MW-4 area)

Well Spacing = 10 feet just downgradient of Tank 53, 22.5 feet in MW-4 area Pumping Rates = 0.25 gpm minimum per recovery well, 3.25 gpm minimum total Width of Capture Zone = 440 feet at widest (upgradient) point in modeled area at

25 gpm/well

Downgradient Extent of Capture Zone = 35 feet beyond line of recovery wells in

MW-4 area at 25 gpm/well.

#### TABLE 5

### SUMMARY OF DESIGN SPECIFICATIONS FOR PROPOSED RECOVERY WELLS CONCEPTUAL REMEDIAL DESIGN – GROUND WATER RESTORATION SITE 13 – TANK FARM FIVE

NAVAL EDUCATION AND TRAINING CENTER, NEWPORT, RHODE ISLAND

#### DOWNGRADIENT SERIES OF WELLS (EW-1 THROUGH EW-8):

TOTAL DEPTH:

**100 FEET** 

**BOREHOLE DIAMETER:** 

12 INCHES

SCREENED INTERVAL:

20 TO 100 FEET BELOW GRADE

SCREEN:

4-INCH STAINLESS STEEL, CONTINUOUS-SLOT, 10-SLOT

RISER:

4-INCH STAINLESS STEEL

PUMP SET DEPTH:

95 FEET BELOW GRADE

#### UPGRADIENT SERIES OF WELLS (EW-9 THROUGH EW-13):

**TOTAL DEPTH:** 

**110 FEET** 

**BOREHOLE DIAMETER:** 

12 INCHES

SCREENED INTERVAL:

20 TO 110 FEET BELOW GRADE

SCREEN:

4-INCH STAINLESS STEEL, CONTINUOUS-SLOT, 10-SLOT

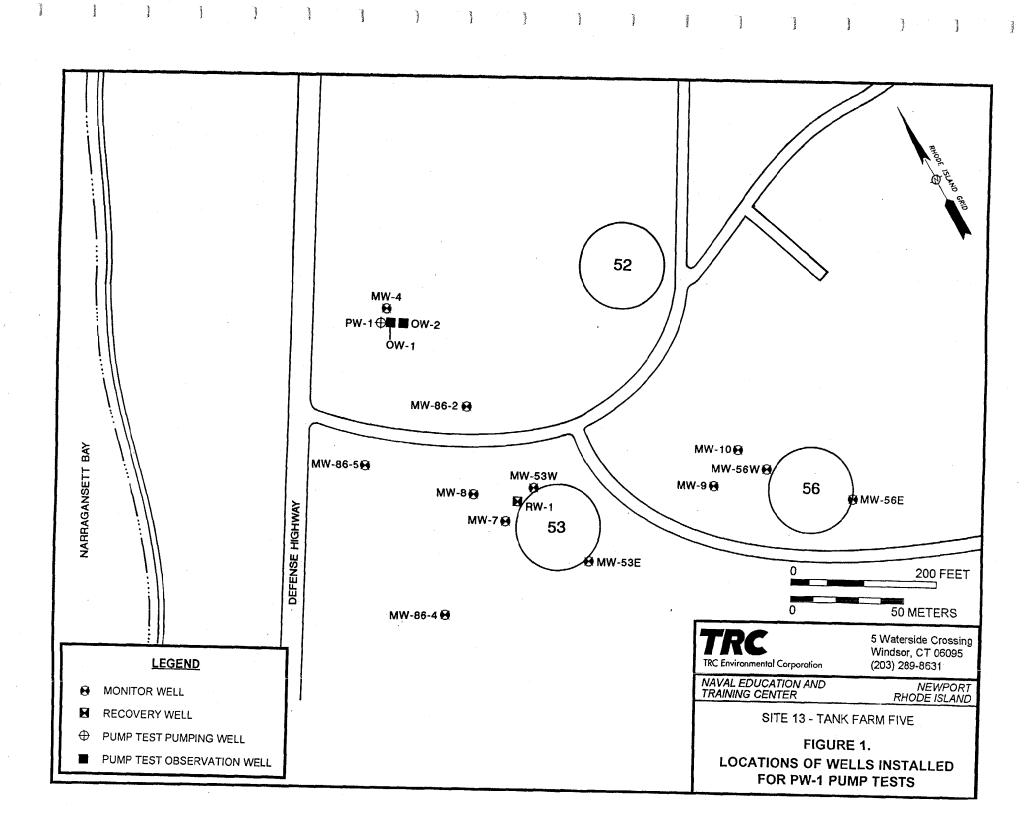

RISER:

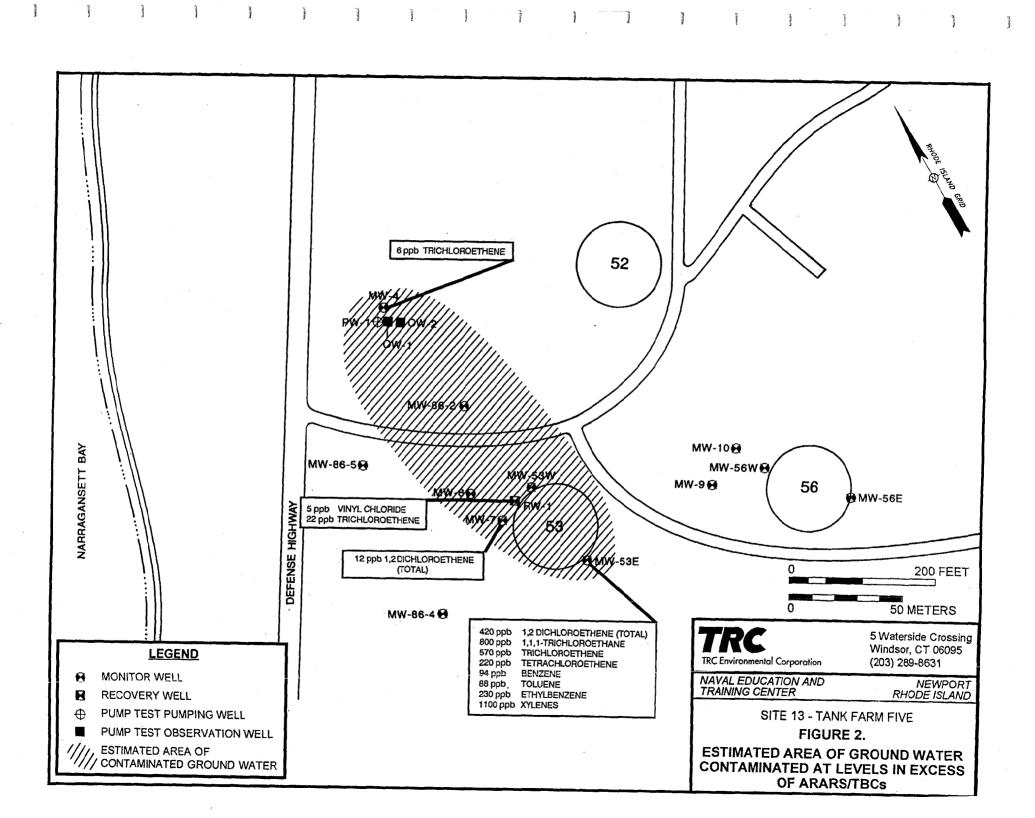

4-INCH STAINLESS STEEL

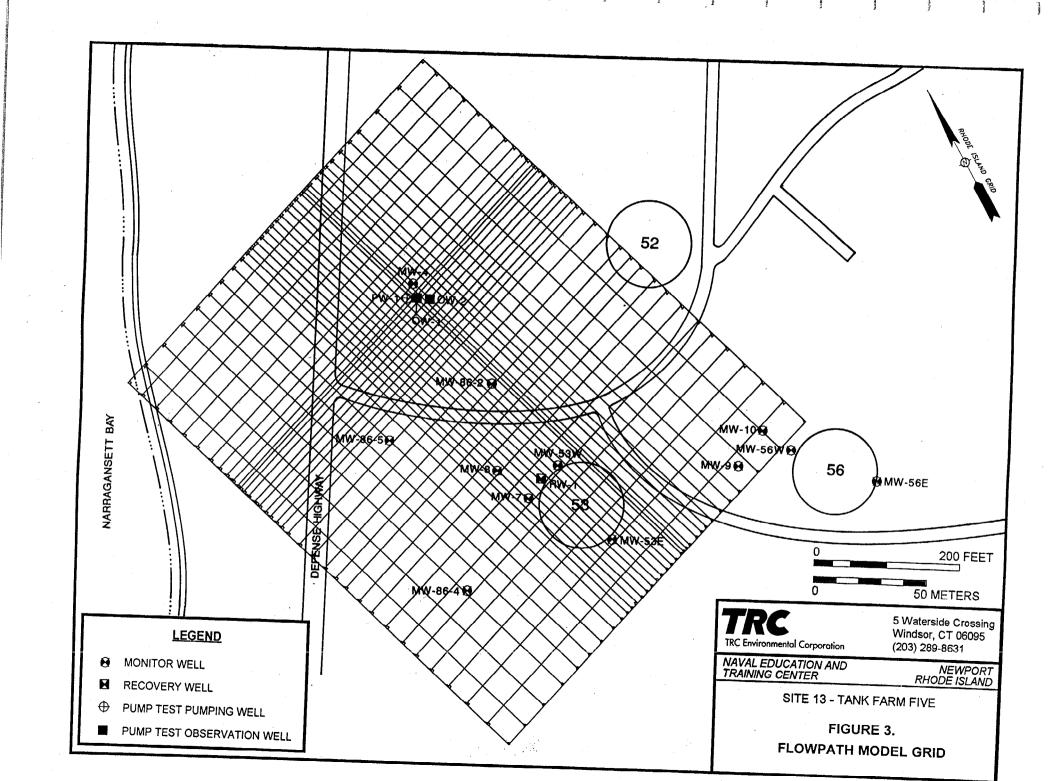

PUMP SET DEPTH:

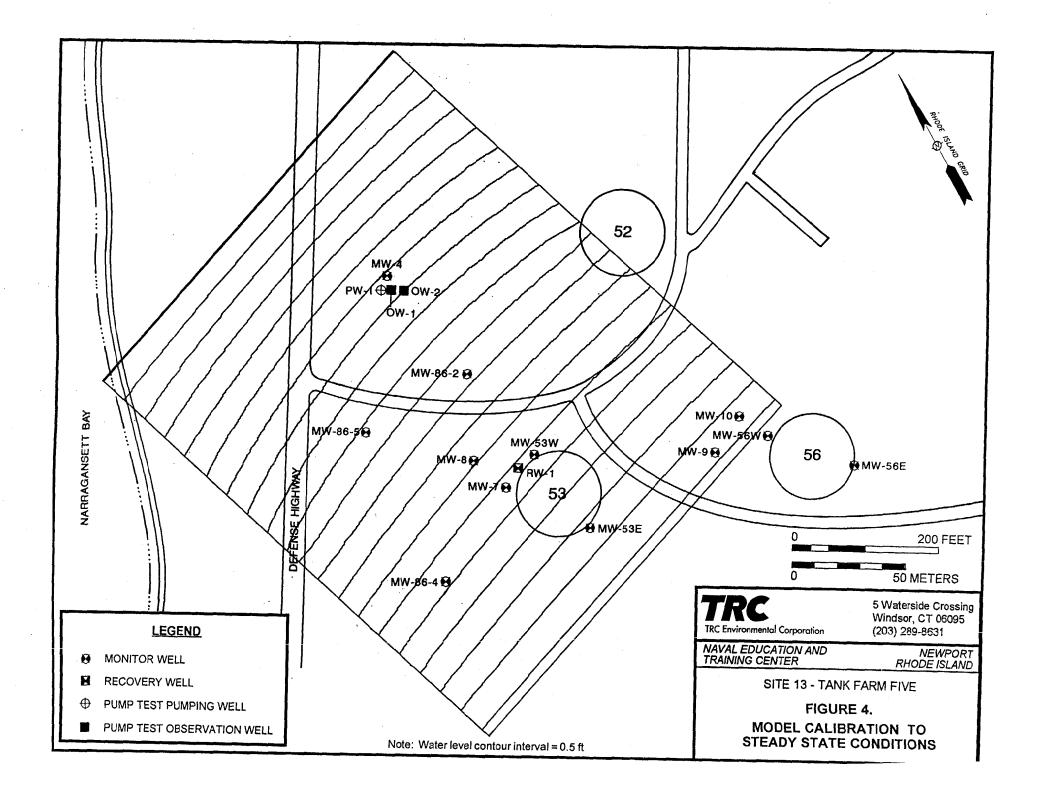

105 FEET BELOW GRADE

Newport, RI 02841

RE: Newport POTW Industrial User Permit Application for Interim Remedial Action - Groundwater Treatment at Tank Farm 5 TRC Project No. 12773-Q41-01

Dear Capt. Rigby:

Enclosed please find the completed Industrial User Permit Application and supporting information to discharge wastewater from Tank Farm 5 to the Newport POTW.

TRC has designed the proposed treatment system for contaminated ground-water at Tank Farm 5. Effluent from the proposed treatment system will flow by gravity to the existing sanitary sewer in the area of the Fire Fighting Training Center for eventual discharge to the Newport POTW.

The following is submitted in support of the permit application:

- 1.0 Purpose
- 2.0 Description
- 3.0 Flow Quantity and Duration
- 4.0 Treatment System Process Summary
- 5.0 Operation and Maintenance Plan
- 6.0 Spill Prevention and Control
- 7.0 Treated Water Effluent Monitoring
- 8.0 Point of Sewer Connection
- 9.0 Newport POTW Industrial User Permit Application

Please call me if you request further information.

Very truly yours,

TRC ENVIRONMENTAL CORPORATION

Ronald J. Nault, P.E.

C-2	GENERAL SITE PLAN	
M-1	TREATMENT EQUIPMENT LAYOUT	

#### 1.0 PURPOSE

The purpose of the proposed connection, which will ultimately result in treated groundwater being discharged to the Newport POTW, is to clean-up fuel oil-contaminated groundwater surrounding the underground storage tanks at Tank Farm 5. Tank Farm 5 is located at the Naval Education and Training Center (NETC) in Newport, Rhode Island (see Figure 1).

#### 2.0 DESCRIPTION

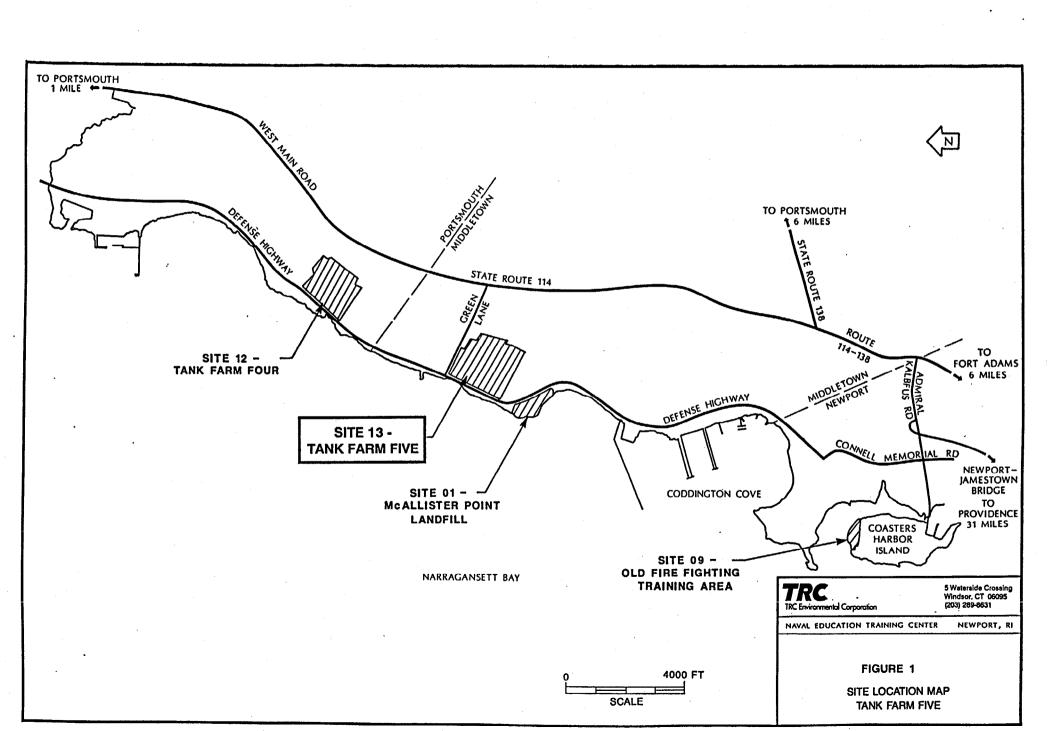

Groundwater in the area of Tank Farm 5 that contains contaminants exceeding the Safe Drinking Water Act maximum levels will be extracted and pumped to a central location for treatment. Inorganic and organic contaminant concentrations will be reduced in the treatment process to levels below the Newport POTW discharge limitations. The treated groundwater will flow by gravity to the existing sanitary sewer system installed for the Fire Fighting Training Facility (see Drawing C-2).

#### 3.0 FLOW QUANTITY AND DURATION

The treatment system will be designed with a capacity of 50 gallons per minute (gpm) or 72,000 gallons per day (gpd). The groundwater extraction rate will be less than the treatment capacity and occur for an undetermined period of time until drinking water standards have been met.

#### 4.0 TREATMENT SYSTEM PROCESS SUMMARY

Testing of the groundwater quality shows that inorganic compounds (metals) and volatile organic contaminants must be reduced as a pretreatment step prior to discharge to the Newport POTW. (See Appendix A for raw water quality data). A treatment system has been selected consisting of a flocculator/clarifier and pressure media filter to precipitate and remove inorganics

coupled with an ultraviolet light/oxidation chamber and granular activated carbon adsorption units to remove organics.

Figure 2 shows a process block flow diagram of the major treatment units and the various points of chemical adjustment, pumps and surge tanks required. Drawing M-l shows the treatment equipment layout contained in a central building. The predicted water quality effluent from the treatment system is shown in Appendix A.

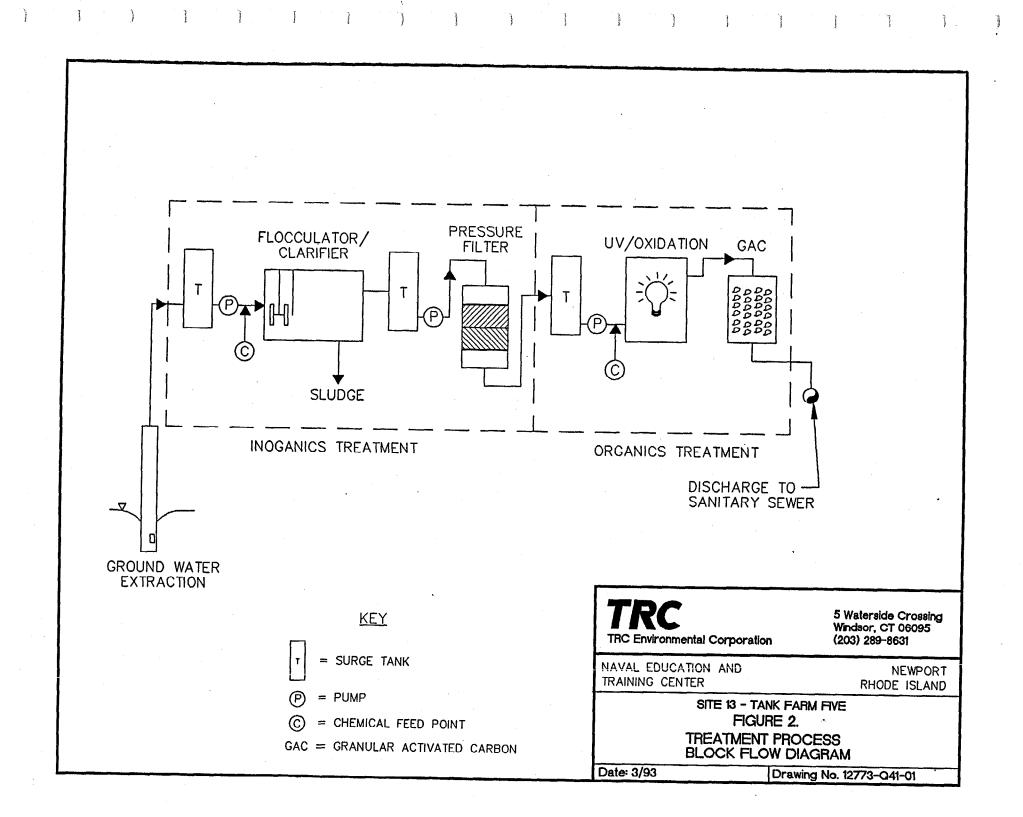

#### 5.0 OPERATION AND MAINTENANCE PLAN

The treatment system will require an operator to monitor and adjust the equipment but will be equipped with complete sensors, instrumentation and controls for automated operation as well as emergency shut-down. All equipment will be provided with high level or failure sensors that will be interlocked to shut down the other processes and minimize system by-pass or accidental release. A detailed Operation and Maintenance Plan will be developed for the groundwater extraction and treatment system. The plan will include the following:

- Standard Operating Procedures
- Equipment Description and Maintenance
- Discharge Permit Requirements
- Monitoring and Reporting Procedures
- Emergency Operating Procedures
- Spill Response and Reporting
- Safety Procedures and Equipment

#### 6.0 SPILL PREVENTION AND CONTROL

The treatment building will be constructed with a floor drain system to collect any spills of process water or treatment chemicals. The floor drains will be recycled to the influent of the treatment system. A detailed Spill Prevention and Control Plan will be developed for the treatment system.

#### 7.0 TREATED WATER EFFLUENT MONITORING

It is proposed that the following constituents will be sampled and submitted to a RIDEM-certified laboratory for EPA-approved analysis:

Parameter	Frequency	<u>Parameter</u>	Frequency
Cadmium	Monthly	Sulfides	Monthly
Chromium (trivalent)	Monthly	Sulfates	Monthly
Chromium (hexavalent)	Monthly	Floating Oil	Monthly
Copper	Monthly	Fluoride	Monthly
Gold	Monthly	Mercuric Chloride	Monthly
Lead	Monthly	Phenols	Monthly
Nickel	Monthly	Total Toxic Organics	Monthly
Silver	Monthly	Suspended Solids	Monthly
Tin	Monthly	BOD	Monthly
Zinc Cyanides	Monthly .	рН	Monthly

The proposed monitoring location is the sampling port at the end of the treatment system inside the new treatment building. The proposed Newport POTW discharge limitations are shown in Appendix A.

#### 8.0 POINT OF SEWER CONNECTION

Treated water will flow by gravity in an 8" sanitary sewer to the existing sewer adjacent to the Fire Fighting Training Facility (see Drawing C-2). From this point of entry into the NETC sewer system, sewage will flow by gravity and in pumped force mains southerly along Defense Highway to eventual discharge to the Newport POTW.

#### 9.0 NEWPORT POTW INDUSTRIAL USER PERMIT APPLICATION

The completed permit application is contained in Appendix B according to the Newport POTW guidelines.

## APPENDIX A

RAW WATER QUALITY, PREDICTED TREATMENT PLANT EFFLUENT AND PROPOSED NEWPORT POTW DISCHARGE LIMITATIONS

The following table lists the predicted average raw water quality from the groundwater extraction wells, the predicted effluent water quality from the treatment system that will be discharged to the sanitary sewer and the proposed limitations for discharge to the Newport POTW.

TABLE 1
